Scope of this document .................................................................................................................. 1
Table of acronyms .......................................................................................................................... 1

1 Design requirements for bridges ................................................................................................ 4
1.1 Reference documents .................................................................................................................. 4
1.2 Bridges – scope .......................................................................................................................... 10
1.2.1 Standard bridges .................................................................................................................. 10
1.2.2 Small and medium span, unusual geometry ...................................................................... 11
1.2.3 Non-standard bridges .......................................................................................................... 11
1.2.4 Structural forms requiring approval .................................................................................. 12
1.2.5 Access for people with disabilities to public transport ....................................................... 13
1.3 Bridge width limitations for maintenance and inspection ...................................................... 13
1.3.1 Division of superstructure .................................................................................................. 13
1.3.2 Under-bridge inspection ..................................................................................................... 14
1.3.3 Jacking for bearing replacement .......................................................................................... 15
1.4 Stage construction and provision for future widening ............................................................ 16
1.4.1 Future widening .................................................................................................................. 16
1.4.2 Stage construction ............................................................................................................. 16
1.4.3 Widening an existing bridge .............................................................................................. 16
1.4.4 Widening two bridges on separate carriageways ............................................................... 17
1.4.5 Estimating residual life of existing bridge .......................................................................... 17
1.4.6 Working with asbestos in bridge rehabilitation works .......................................................... 18
1.5 Quality assurance in design documentation ............................................................................ 19
1.5.1 Structural design objectives ............................................................................................... 19
1.5.2 Conforming product, alternative product and innovation .................................................. 20
1.5.3 Review of drawings and scheme documents ...................................................................... 20
1.6 Bridge design report ............................................................................................................... 21
1.6.1 Phases of report .................................................................................................................. 21
1.6.2 Fixing report – bridge location determined ....................................................................... 21
1.6.3 15% complete design report .............................................................................................. 21
1.6.4 50% complete design report .............................................................................................. 22
1.6.5 85% complete design report .............................................................................................. 22
1.6.6 Final design report ............................................................................................................. 22
1.7 Design certification .................................................................................................................. 23
1.8 Innovative materials and components .................................................................................... 23
1.9 ‘As Constructed’ drawings and construction handover report ................................................. 24

2 Bridge aesthetics .......................................................................................................................... 25
2.1 General ...................................................................................................................................... 25
2.2 Anti-graffiti coating .................................................................................................................. 25

3 Bridge functional requirements .................................................................................................. 27
3.1 Traffic capacity .......................................................................................................................... 27
3.1.1 Number of lanes and bridge carriageway width .................................................................. 27
3.1.2 Clearances and shoulder width ............................................................................................ 31
3.1.3 Geometry, design speed ...................................................................................................... 32
3.2 Load capacity – freight efficiency ............................................................................................. 32
3.2.1 Design loads and construction sequence ............................................................................ 32
3.2.2 Design traffic loads for new bridges .................................................................................... 32
3.2.3 Design traffic loads for widening / strengthening an existing bridge .................................. 33
3.2.4 Design traffic loads for damaged bridges .......................................................................... 36
3.2.5 Heavy Load Platforms (HLPs) ................................................................. 36
3.2.6 Abnormal loads...................................................................................... 36
3.2.7 Special conditions for footbridges ............................................................ 36
3.2.8 Design traffic loads for busway bridges .................................................... 36
3.2.9 Design traffic loads for light rail passenger transit bridges ...................... 38
3.3 Load capacity – environmental and construction loads............................. 39
  3.3.1 Mining subsidence ................................................................................. 39
3.4 Hydraulic investigation, flood loadings and levels ...................................... 40
  3.4.1 Hydraulic investigation .......................................................................... 40
  3.4.2 Minimum hydraulic forces on bridges .................................................... 41
3.5 Construction loads ..................................................................................... 41
  3.5.1 Incrementally launched prestressed concrete bridges .............................. 41
3.6 Construction loads all bridges .................................................................... 42
3.7 Sustainability............................................................................................... 42
  3.7.1 Design life – new bridges ....................................................................... 42
  3.7.2 Design life for drainage structures ........................................................ 43
  3.7.3 Design life – remedial works ................................................................. 43
3.8 Durability – bridges .................................................................................... 43
  3.8.1 Steelwork .............................................................................................. 43
  3.8.2 Fitments material .................................................................................... 43
  3.8.3 Painted steel structures .......................................................................... 44
  3.8.4 Durability for concrete .......................................................................... 45
3.9 Buried components (no inspection, maintenance practical) ......................... 48
3.10 Aggressive environments .......................................................................... 48
  3.10.1 Sulphate reducing bacteria ................................................................. 48
  3.10.2 Stray currents from electric railway or other sources ........................... 48
  3.10.3 Bridge components in marine environment ........................................... 48
3.11 Cracks in concrete at the end of construction .......................................... 49
3.12 Thermal cracking in large sections – modelling in design ....................... 49
3.13 Economy ................................................................................................... 50
  3.13.1 Minimum whole-of-life costs ............................................................... 50
  3.13.2 Design details for economy .................................................................. 50
  3.13.3 Constructability .................................................................................... 50
  3.13.4 Maintainability ..................................................................................... 50
3.14 Acceptable level of afflux .......................................................................... 50
3.15 Protection against scour ........................................................................... 50
  3.15.1 Scour at abutments and piers ............................................................... 51
  3.15.2 Handling drainage from adjacent road ................................................. 52
  3.15.3 Scour on drawings ............................................................................... 52
3.16 Safety in design, construction and maintenance ...................................... 52
  3.16.1 Safe access to site ................................................................................ 52
  3.16.2 Safe access for inspections (stairs, ladders, hatches, anchorage points) 52
3.17 Bridge security (when specified) ................................................................. 52
3.18 Bridges over / in the proximity to railway .................................................. 52
3.19 Special conditions or requirements ............................................................ 54
4 Bridge component design requirements .......................................................... 55
  4.1 Foundation design .................................................................................... 55
    4.1.1 Driven piles – structural design ........................................................... 55
    4.1.2 Cast-in-place piles – structural design .................................................. 55
    4.1.3 Pile design outputs shown in drawings ................................................. 56
Design Criteria for Bridges and Other Structures, Transport and Main Roads, February 2018
4.14 Footbridges and bikeways ........................................................................................................ 94
4.14.1 Special conditions for short span, narrow footbridges not over road or rail corridor ... 94
4.14.2 Maximum gradient .............................................................................................................. 94
4.15 Paint systems ........................................................................................................................... 94
4.15.1 Initial application to be compatible with future recoating .................................................. 94
4.15.2 Medium exposure (C3 to AS 2312 and AS 4312) ............................................................. 95
4.15.3 Very high marine exposure (C5M to AS 2312 and AS 4312) ............................................. 95
4.16 Structural steel ....................................................................................................................... 95
5 Additional requirements – bridges ............................................................................................ 96
5.1 Date plates and survey marks .................................................................................................. 96
5.2 Inspection during construction and on completion of bridges .................................................. 96
5.2.1 Inspection on completion of construction ........................................................................... 96
5.2.2 Multi-span bridges .............................................................................................................. 96
6 Additional requirements to AS 5100 Bridge design ................................................................... 97
7 Matters for resolution to AS 5100 ............................................................................................... 104
8 Tunnel design requirements ....................................................................................................... 117
8.1 Design and construction of tunnel structures ......................................................................... 117
8.1.1 Scope ...................................................................................................................................... 117
8.1.2 Design, construction and operation criteria ......................................................................... 117
8.1.3 Useful references in design and construction of tunnels ..................................................... 117
8.1.4 Design objectives ................................................................................................................ 118
8.2 Geological/Geotechnical Investigations for tunnels ................................................................. 120
8.3 Design life – tunnels ................................................................................................................ 120
8.4 Durability .................................................................................................................................. 121
8.5 Dislodging of overhead equipment ......................................................................................... 122
8.6 Hydraulics and drainage ......................................................................................................... 122
8.7 Fire and life safety .................................................................................................................. 123
8.8 Design criteria ........................................................................................................................ 125
8.8.1 General ................................................................................................................................... 125
8.8.2 Road and bus tunnels – additional requirements ................................................................. 126
8.8.3 Design criteria – driven tunnel ............................................................................................ 126
8.8.4 Design criteria – cut and cover tunnel ................................................................................ 127
8.8.5 Parametric study .................................................................................................................. 128
8.9 Design loads ............................................................................................................................ 128
8.9.1 Live loadings ........................................................................................................................ 128
8.10 Structural design ................................................................................................................... 130
8.11 Mechanical and electrical services and ITS ........................................................................... 130
8.12 Review of drawings and scheme documents ........................................................................... 130
8.13 Design report ........................................................................................................................ 131
8.13.1 Incident management and recovery manual ..................................................................... 132
8.14 Construction .......................................................................................................................... 132
8.14.1 Construction Specifications ............................................................................................... 132
8.14.2 Instrumentation .................................................................................................................. 133
8.14.3 Design validity check during construction ........................................................................ 133
8.14.4 Validation of permanent anchors .................................................................................... 133
8.15 “As Constructed” drawings and construction handover report ........................................... 135
8.15.1 Fire and life safety report ..................................................................................................... 135
9 Development application in the proximity to tunnels ................................................................. 137

9.1 Purpose................................................................................................................................ 137

9.2 State-controlled tunnels in south east Queensland................................................................. 137

9.3 Development approval requirements ..................................................................................... 139

9.3.1 Zone of influence for tunnels ......................................................................................... 139

9.3.2 Permissible excavation above and beside a tunnel and within the easement area... 140

9.3.3 State-controlled future tunnel assessment requirements ................................................. 141

9.3.4 State-controlled existing tunnel design assessment requirements ................................ 142

9.3.5 Building load calculations ............................................................................................... 144

9.4 Pre-construction, construction and post construction compliance requirements ............... 145

9.4.1 Potholing....................................................................................................................... 145

9.4.2 Demolition: risk assessment and method statement......................................................... 145

9.4.3 Foundation excavation survey ....................................................................................... 146

9.4.4 Tunnel dilapidation survey ........................................................................................... 146

9.4.5 Tunnel monitoring requirements.................................................................................... 147

9.4.6 Ground water monitoring ............................................................................................. 149

9.4.7 Tunnel movement monitoring........................................................................................ 149

9.4.8 Vibration monitoring...................................................................................................... 150

9.4.9 Crack monitoring device.................................................................................................. 152

9.4.10 Ground movement adjacent to the tunnel ..................................................................... 152

9.5 Additional requirements for tunnels ..................................................................................... 153

10 Gantries and support structures ............................................................................................... 155

10.1 Applicability ......................................................................................................................... 155

10.2 Provision of ITS devices and support structures................................................................. 155

10.3 Clearance ............................................................................................................................... 156

10.4 Additional design requirements .......................................................................................... 156

10.4.1 Design life .................................................................................................................... 156

10.4.2 Live load ...................................................................................................................... 156

10.4.3 Aesthetics .................................................................................................................... 156

10.4.4 Corrosion protection and durability ............................................................................ 156

10.4.5 Concrete durability ....................................................................................................... 156

10.4.6 Serviceability deflection............................................................................................... 157

10.4.7 Vibration ...................................................................................................................... 158

10.4.8 Foundations design ....................................................................................................... 158

10.5 Structural design.................................................................................................................. 160

10.5.1 Wind loading................................................................................................................ 160

10.5.2 Structural design criteria fatigue ................................................................................ 160

10.5.3 Load combinations ......................................................................................................... 160

10.5.4 Signs attached to bridges – additional design criteria ............................................... 160

10.6 Design of elements for structures....................................................................................... 162

10.6.1 Maintenance platform .................................................................................................. 162

10.6.2 Access ladder and landings ......................................................................................... 163

10.6.3 Access to the structure site .......................................................................................... 166

10.6.4 Wiring enclosures ......................................................................................................... 166

10.6.5 Bolts, nuts and washers ............................................................................................... 166

10.6.6 Anchor bolt/rod details ............................................................................................... 167

10.6.7 Base plate thickness ..................................................................................................... 167

10.6.8 Structural steel ............................................................................................................. 167

10.6.9 Provision for drawing cables and wiring ..................................................................... 167

10.7 Drawings and design report ................................................................................................. 167
10.8 Transport and Main Roads review of drawings and design report ........................................... 168
10.9 Fabrication of structural steelworks and aluminium components ........................................ 169
10.10 Installation of structure ........................................................................................................ 169
10.11 Inspection ............................................................................................................................. 170
10.12 Protection of sign structures from vehicle impact ............................................................... 170
  10.12.1 Barrier deflection restrictions ....................................................................................... 170
  10.12.2 Working width restrictions ......................................................................................... 170
  10.12.3 Special design requirements ....................................................................................... 171
  10.12.4 Traffic barrier design criteria ...................................................................................... 171

11 Roadside advertising signs ........................................................................................................ 174
11.1 Applicability .......................................................................................................................... 174
11.2 Sign licensee .......................................................................................................................... 175
11.3 Administrator ........................................................................................................................ 175
11.4 Design criteria for on-carriageway advertising signs ............................................................. 175
  11.4.1 Vertical clearance .......................................................................................................... 175
  11.4.2 Advertising signs attached to bridges ........................................................................... 176
  11.4.3 Aesthetics ...................................................................................................................... 177
  11.4.4 Materials ....................................................................................................................... 177
  11.4.5 Structural design ......................................................................................................... 178
  11.4.6 Corrosion protection and durability ............................................................................. 182
  11.4.7 Concrete durability ....................................................................................................... 182
  11.4.8 Maintenance platform ................................................................................................. 182
  11.4.9 Access ladder and landings .......................................................................................... 183
  11.4.10 Wiring and wiring enclosures ...................................................................................... 186
  11.4.11 Access to the structure site ....................................................................................... 186
  11.4.12 Protection of structures from vehicle impact ............................................................ 186
  11.4.13 Transport and Main Roads review of drawings and scheme documents .................. 186
  11.4.14 Quality assurance in the documentation ................................................................... 187
  11.4.15 Design certification ..................................................................................................... 188
  11.4.16 Acceptance for fabrication and construction ............................................................. 189
  11.4.17 Fabrication of structural steelworks and aluminium components ............................ 189
  11.4.18 Installation of the structure ....................................................................................... 189
  11.4.19 Inspection of the installed sign structure ................................................................. 191
11.5 Design criteria for off-carriageway advertising signs ............................................................ 192
  11.5.1 Vertical clearance ........................................................................................................ 192
  11.5.2 Materials ....................................................................................................................... 192
  11.5.3 Structural design ......................................................................................................... 193
  11.5.4 Corrosion protection and durability ............................................................................. 194
  11.5.5 Maintenance platform ................................................................................................. 194
  11.5.6 Wiring and wiring enclosures ...................................................................................... 194
  11.5.7 Protection of structures from vehicle impact ............................................................ 194
  11.5.8 Construction specifications .......................................................................................... 194
  11.5.9 Transport and Main Roads design acceptance ............................................................. 194
  11.5.10 Design certification ..................................................................................................... 195
  11.5.11 Fabrication of structural steelwork ........................................................................... 195
  11.5.12 Construction supervision .......................................................................................... 196
  11.5.13 Inspection .................................................................................................................. 196
11.6 Provisions of fall protection to existing roadside advertising signs ......................................... 196
11.7 Approval flow charts .............................................................................................................. 198
12 Buried concrete arch design requirements .............................................................................. 200
12.1 Scope ..................................................................................................................................... 200
12.2 Design life and serviceability ................................................................. 200
12.3 Quality assurance in design and documentation ........................................ 200
  12.3.1 Design acceptance process ............................................................... 200
12.4 Design criteria ....................................................................................... 201
12.5 Other requirements ................................................................................ 204
12.6 Concrete durability ................................................................................ 204
12.7 Development adjacent to arches ............................................................ 204
12.8 Arch manufacturing criteria ................................................................. 205
13 Retaining structures .................................................................................. 206
  13.1 Design requirements for retaining walls .................................................... 206
  13.2 Design life of retaining structures ............................................................ 206
  13.3 Design certification ................................................................................ 206
    13.3.1 Structural design ............................................................................. 206
    13.3.2 Design certification – additional requirements ................................... 207
  13.4 Quality assurance for design and construction .......................................... 207
  13.5 Aesthetics ............................................................................................. 207
    13.5.1 Flood loading .................................................................................... 208
    13.5.2 Tiered walls ..................................................................................... 208
    13.5.3 Control joint for prevention of cracks in retaining walls ..................... 208
  13.6 Retaining wall drainage ......................................................................... 208
  13.7 Design calculations ............................................................................... 208
  13.8 Additional requirements for Reinforced Soil Structure (RSS) retaining walls 208
    13.8.1 Impact protection from Road traffic .................................................... 209
    13.8.2 Impact protection from rail traffic ....................................................... 209
    13.8.3 Mine haul vehicle impact ................................................................. 210
  13.9 Additional requirements for piles in retaining walls ................................ 210
    13.9.1 Cast-in place piles for high moment, low axial load applications ......... 210
    13.9.2 Contiguous piled walls .................................................................... 211
  13.10 Additional requirements for block masonry retaining walls .................... 211
14 Busway stations, light rail stations and ancillary structures ......................... 213
  14.1 Design life ......................................................................................... 213
  14.2 Materials ............................................................................................ 213
    14.2.1 Concrete class .................................................................................. 213
    14.2.2 Structural steel ................................................................................ 213
  14.3 Design criteria ..................................................................................... 213
    14.3.1 Column base plate details ................................................................. 214
    14.3.2 Foundation types not permitted by the department ......................... 214
    14.3.3 Corrosion protection for structural steelworks .................................... 214
  14.4 Durability for concrete ......................................................................... 215
15 Development application in the proximity to bridges and other structures including transport infrastructures ......................................................... 216
  15.1 General .............................................................................................. 216
  15.2 Drawings, reports and method statements ............................................... 216
  15.3 Potholing criteria ................................................................................ 217
  15.4 Demolition phase ................................................................................ 217
15.5 Construction phases ........................................................................................................... 217
15.6 Additional criteria for development adjacent to bridges .................................................. 218

16 Design of Fibre Reinforced Polymer (FRP) composite girders ......................................... 222
16.1 Scope and application ........................................................................................................ 222
16.2 Symbols and notations ...................................................................................................... 222
16.3 Provision for innovation .................................................................................................... 222
16.4 Maximum operating temperature .................................................................................... 224
16.5 Exclusions .......................................................................................................................... 225
16.6 Material properties ........................................................................................................... 225
  16.6.1 General ....................................................................................................................... 225
  16.6.2 Reinforcement ............................................................................................................ 225
  16.6.3 Polymer matrices ....................................................................................................... 226
  16.6.4 Core materials ........................................................................................................... 226
  16.6.5 Gel coats ................................................................................................................... 227
  16.6.6 Laminates .................................................................................................................. 227
  16.6.7 FRP profiles .............................................................................................................. 227
16.7 Design and detailing ......................................................................................................... 227
  16.7.1 Design for ultimate limit state ................................................................................... 227
  16.7.2 Design for serviceability limit state .......................................................................... 228
  16.7.3 Warning of failure ..................................................................................................... 228
  16.7.4 Failure modes ............................................................................................................ 228
  16.7.5 Design for stability .................................................................................................... 229
  16.7.6 Deformability of FRP composite girders .................................................................... 229
  16.7.7 Durability .................................................................................................................. 229
  16.7.8 Fire resistance .......................................................................................................... 229
  16.7.9 Thermal expansion ................................................................................................. 230
  16.7.10 Creep and shrinkage ............................................................................................... 230
  16.7.11 End zones design and connections ....................................................................... 230
16.8 Design requirements .......................................................................................................... 232
16.9 Additional requirements FRP composite girders for new bridges .................................... 232
  16.9.1 Traffic loads on new bridges .................................................................................... 232
  16.9.2 Load combinations and load factors for design of FRP composite girders .............. 232
  16.9.3 Method of structural analysis and design .................................................................. 232
  16.9.4 Design for strength .................................................................................................... 232
  16.9.5 Deflection ................................................................................................................ 233
  16.9.6 Design life ................................................................................................................ 233
  16.9.7 Fatigue for FRP girders on new bridges ................................................................. 233
  16.9.8 Vibration .................................................................................................................. 233
16.10 Additional design requirements for FRP composite girders on existing timber bridges .... 233
  16.10.1 Performance criteria ............................................................................................... 233
  16.10.2 Fatigue design of FRP composite girders on timber bridges ................................. 234
  16.10.3 Design Life of FRP composite girders on timber bridges .................................. 234

17 Small drainage structures .................................................................................................... 235
17.1 Design requirements for culverts ...................................................................................... 235
17.2 Design life for small drainage structures ......................................................................... 235
17.3 Barriers for culverts .......................................................................................................... 236
17.4 Approach settlement adjacent to large culverts ............................................................... 236
17.5 Structural requirements for existing culverts .................................................................... 236

18 Design of motor grids .......................................................................................................... 237

**Scope of this document**

This criterion covers requirements for the design of bridges and other road-related structures as listed below:

- bridges carrying road traffic
- pedestrian and cycle bridges
- bridges carrying light rail traffic
- bridges carrying busway traffic
- underpasses and overpasses for road traffic, pedestrian or cycle paths
- tunnels
- gantries and traffic sign support structures
- roadside advertising sign support structures
- retaining walls and other associated structures
- small drainage structures including culverts
- noise barriers
- fauna crossings
- concrete arches
- submerged structures
- bus stations, light rail stations and ancillary structures
- Fibre Reinforced Polymer Composite (FRPC) girders for timber bridge rehabilitations, and
- development applications adjacent to transport infrastructure.

1 Design requirements for bridges

Chapters 1 to 7 apply for bridges including overpasses and underpasses that are required to support road traffic loads, pedestrian and cycle loads, busway traffic loads and light rail traffic loads.

Refer Section 17 for small drainage structures including culverts.

1.1 Reference documents

a) This set of design criteria complements AS 5100 Bridge design. Where this document and AS 5100 disagree, this document takes precedence.

b) AS 5100 is defined as: AS 5100:2004 series which comprises following parts:
   i. AS 5100.1 Bridge Design – Scope and general principles
   ii. AS 5100.2 Bridge design - Design loads
   iii. AS 5100.3 Bridge design - Foundation and soil-supporting structures
   iv. AS 5100.4 Bridge design - Bearings and deck joints
   v. AS 5100.5 Bridge design – Concrete
   vi. AS/NZS 5100.6 Bridge design - Steel and composite construction
   vii. AS 5100.7 Bridge design – Rating of Existing Bridges.

and its current Supplements and the Amendments issued.

c) Amendments and corrections to AS 5100 are set out in Chapter 6 of this document.

d) At the start of each bridge design project, the additional requirements in Section 7 Matters for resolution to AS 5100 shall be either:
   i. supplied by the Principal to the Designer, or
   ii. a proposal for the contents of Section 7 shall be prepared by the Designer, and submitted to the Director (Structures Review and Standards) for modification (if necessary) and acceptance.

e) The design of transversely stressed prestressed concrete deck units shall also be based on Standard Drawing 2042 – Precast Units – Design assumptions for transversely stressed standard deck units.

f) Construction shall be in accordance with the Department of Transport and Main Roads’ Technical Specifications.

g) The Standard Drawings and Specifications referenced in this document are the latest versions, published on the department’s website www.tmr.qld.gov.au.

h) All project drawings shall be completed to the standards of detailing, accuracy and completeness set out in the Transport and Main Roads Drafting and Design Presentation Standards, Volume 3, Structural Drafting Standards.

i) Where Transport and Main Roads’ Structures Inspection Manual does not explicitly cover the inspection and maintenance of any bridge component or novel material or coating, the Designer shall provide procedures for inspection and maintenance for the novel aspects of the design.
Chapter 1: Design requirements for bridges

j) These criteria relate to Transport and Main Roads bridges. Bridges involving other authorities may have different requirements, for example:

- Queensland Rail (clearances, structural form)
- utilities (communications, cables, and so on)
- local authorities (water, sewerage pipes), and
- mining development and power stations (specific load or dimensional clearances on associated roads).

k) The Designer shall consult relevant authorities for their additional requirements if these are not explicitly included in Section 7 Matters for Resolution.

The following table shows the various documents referred to by this document.

### 1.2 Bridges – scope

The scope of these Design Criteria is limited as follows.

#### 1.2.1 Standard bridges

This document covers the following types of bridge superstructure:

- Standard small and medium span bridges including:
  - transversely stressed deck units as detailed on Transport and Main Roads Standard Drawings
  - deck units with reinforced concrete deck slabs
  - super T-girders with reinforced concrete deck slab
  - I-girders similar to AASHTO or NAASRA standard shapes for Prestressed Concrete (PSC) girders

**Note:** Due to the limited availability for following superstructure types, the Director (Structures Review and Standards) shall be consulted prior to commencement of concept design.

- steel I-girders for widening existing bridges with steel I-girders; acceptance to use steel girders in new bridges shall be obtained from the Deputy Chief Engineer (Structures) prior to commencement of design.
- insitu reinforced concrete decks on deck units, prestressed concrete and steel girders, and
• transverse width of a concrete deck not exceeding 20 m: additional criteria for limiting transverse concrete creep and shrinkage apply to wider bridges, and shall be included in a preliminary design report.

b) Small and medium span bridges with proprietary girder types approved by Transport and Main Roads as described in Clause 4.7.10

c) Small and medium span bridges of unusual geometry which require additional design and detailing (see Section 1.2.2).

d) Medium span bridges such as box girders, or curved ramp bridges using box girders, and

e) Footbridges of conventional design.

This document covers the following types of bridge substructure:

a) prestressed concrete driven piles (Transport and Main Roads Standard Drawing 2021: 550 Octagonal PSC Piles – Earthquake classification BEDC-1, Exposure classification) extended up to headstock

b) reinforced concrete cast in situ columns on cast-in-place piles to MRTS63 Cast-In-Place Piles or reinforced concrete footings, and

c) cast in situ reinforced concrete blade wall abutments and piers on spread footings or piles.

1.2.2 Small and medium span, unusual geometry

a) Bridges with one or more of the following characteristics are not preferred and they require additional consideration in design to ensure the behaviour of the bridge in service does not create maintenance problems:

• skews over 45°

• horizontal curvature where the maximum distance between the arc and the chord over a span exceeds 600 mm

• decks over 20 m wide, where transverse concrete creep and shrinkage and temperature movements shall be considered in the design, and the effects reduced as far as practical: refer additional criteria for bridge width in Section 1.3, and / or

• continuous curved superstructure, such as box girders, where the change in angle exceeds 30° – the effects of bearing placement, lateral restraint, thermal movements, and vertical differential temperature inducing torsional effects shall be considered in design.

b) The Designer shall submit a detailed preliminary design report to the Principal on the additional design considerations undertaken and the reasons for the adopted design solutions, prior to submission of any preliminary design drawings for acceptance, typically at the 15% design completed stage.

1.2.3 Non-standard bridges

a) Non-standard bridges include:

• all bridges not included in Sections 1.2.1 and 1.2.2

• all bridges outside the scope of AS 5100

• arch bridges
• pedestrian access to railway platforms
• bridges incorporating structural components made from novel or unusual materials
• bridges incorporating novel or unusual structural forms
• concrete box girder bridges - AS 5100 does not adequately address shear and torsion in large concrete box girder bridges: **AASHTO-Load and Resistance Factor Design (LRFD)** shall be the basis of the acceptance, and
• steel box girders - AS 5100 does not adequately address the design requirements of this structural form.

b) This document does not cover the use and design requirements for non-standard bridges.

c) Any Designer proposing the use of such bridge forms or materials shall submit a detailed proposal before design commences to the Director (Structures Review and Standards) for acceptance, detailing:
• the reasons for use of such non-standard bridge forms or materials
• proposed design standards and materials specifications to be used
• the Designer’s proposal in the use of the materials, structural forms and design standards
• evidence showing that the materials and components will have the specified design life
• one copy of every design standard and material specification, in English and fully legible
• proposals for independent proof engineering of the design by experienced appropriate design consultants with RPEQ, and
• proposals for independent testing for conformance to specifications of all unusual materials proposed in the design. Testing shall be done in Australia, witnessed by a Departmental Representative, all at no additional cost to the Principal.

Design shall not commence until full acceptance is given to use the non-standard designs and materials.

1.2.4 **Structural forms requiring approval**

a) **Integral structures**

Bridges with ‘integral’ substructure and superstructure may be considered in certain situations such as:
• vertical alignment is constrained and an integral structure would achieve a higher vertical clearance and / or flatter longitudinal grade
• extend the span capability of a girder with a given girder length
• access to inspect and replace bridge bearings is severely restricted, and
• the foundation material is of competent quality to limit differential settlement of the abutments and piers to acceptable limits appropriate for the integral structure.

Integral structure design shall include the effects of additional earth pressure due to ‘ratcheting’ of the abutment backfill, based on geotechnical investigation and report, and the
UK Highways Agency (HA) Design Manual for Roads and Bridges, Design of Integral Bridges BA 42/96.

Highly skewed and / or long integral bridges are generally considered unsuitable for integral structural form as it is outside the scope of AS 5100. These can result in ‘unusual’ effects from loads, detrimental effects on the pavement and other effects causing maintenance issues. They need to be addressed, and the design criteria established, during initial option studies for integral bridges and other structural forms.

A combination of cast-in ferrules for reinforcing starter bars, in addition to strands projecting from the end of the girders (or deck units), may be used to reduce the risk of accidental breaking of the strands during handling.

b) Substructure with single columns

In situations where geometric design constraints require a single column at a pier, the risk and consequences of vehicle / vessel impact on the column shall be assessed. AS 5100.1 requires sufficient redundancies to prevent collapse of the structure. The column shall be structurally robust to resist impact because there is no structural redundancy if the single column fails on impact. The column and foundation shall be designed to resist at least twice the structural ultimate limit state capacity required using AS 5100 design loads, in addition to the use of barriers for pier protection. Refer Chapter 6 of this document for requirement of pier protection from impact.

Blade walls with length less than or equal to 75% of the bridge deck width and blade walls for pedestrian bridges shall be considered as a single column for this Section.

To ensure a robust design, the effect of redundancy in the substructure shall be assessed. For this reason, single column piers are non-preferred and will require prior approval. Multi-column piers shall consider the effect of removing any one column due to collision and the structure designed to resist disproportionate collapse using alternative load paths. Single-column pier shall be designed for the higher impact loads to get at least twice the structural capacity required using AS 5100.

1.2.5 Access for people with disabilities to public transport

For bridges that are designed to provide pedestrian access to public transport, the bridge design shall comply with the Australian Government’s Disability Standards for Accessible Public Transport 2002.

1.3 Bridge width limitations for maintenance and inspection

1.3.1 Division of superstructure

The requirements for safe access to carry out inspections and repairs and jacking a bridge to replace bearings have to be considered when deciding on an appropriate width and arrangement of superstructure. This often requires dividing a bridge into twin parallel superstructures.

If there are two or more lanes in each direction and no easy diversion option is available, the bridge must be separated into two superstructures where possible.

The minimum clear gap between bridge decks has to be sufficient for safe construction of the adjacent safety barriers between the bridges and with a minimum of 250 mm. A wider superstructure gap may be required to meet the bridge inspection provisions in accordance with Section 1.3.2. Where it is not
possible to provide split superstructures with the appropriate gaps, alternative access options shall be assessed and referred to the Deputy Chief Engineer (Structures) for advice.

*Figure 1.3.1 – Minimum gap between adjacent bridge decks*

Usually the network owner requires a road to remain open to traffic during maintenance operations and specifically replacement of bridge bearings. Structural engineering analysis and practical jacking operations, however, require the whole superstructure width to be lifted off the abutment simultaneously to replace bridge bearings, which prohibits traffic from using the bridge during the jacking operation. A side track or traffic diversion onto alternative routes is often not possible due to terrain, property boundaries, detour distances and so on, and the resulting financial and social cost to the community is unacceptable. Separating the superstructure allows traffic to be temporarily diverted onto the adjacent bridge structure using contra-flow. Disruption to the road network is minimised and total road closure, which is increasingly unacceptable to the network owner, is avoided.

Separating a wide superstructure also reduces the risk of cracking in the deck and is beneficial to the structural behaviour of the bridge especially on highly skewed bridges (skewed deck, bearings and substructure). It also simplifies structural analysis and reduces construction risks.

### 1.3.2 Under-bridge inspection

The method of gaining access to the underside of the bridge for inspection and maintenance depends on a number of factors and should consider all relevant factors, including location (over a road, water, rail, adjacent properties), access method (from the deck or from below), height (for access from below) and site-specific constraints (access from deck may be the only safe and practical option).

Where maintenance and inspection access is not practical from the ground, under-bridge inspection is usually carried out using an Under Bridge Inspection Unit (UBIU). Currently, available UBIUs have a maximum working reach of 15–17 m under the bridge (based on UBIU ABC Unit version ABC 160/LS), ref Figure 1.3.2. Bridge superstructures up to 30 m wide can be inspected by positioning the UBIU on each side of the deck to achieve the full coverage, although the vehicle position on the deck has to be considered, which may reduce the width of coverage. When the UBIU vehicle is closer to the edge than the minimum distance of 2.85 m (see Figure 1.3.2), the working reach will be less or if there is a pedestrian / bicycle shared path with raised kerb on the deck, the UBIU vehicle will be positioned further away and the maximum outreach distance must be considered.
Wider bridges that do not meet the above criteria for UBIU access shall be divided and designed as separate structures. The minimum clear separation distance between structures shall be as noted in Section 1.3.1. Where the combined total width of both structures is more than 30 m the UBIU has to be lowered between the structures to gain access and the clear gap between bridges shall be a minimum of 2.0 m to safely lower the platform and rotate into position. Refer to Section 1.3.3 for additional bridge width limitations to allow for future jacking and bearing replacement.

**Figure 1.3.2 – Typical Under Bridge Inspection Unit (UBIU) arrangement**

### 1.3.3 Jacking for bearing replacement

Bridge width is a critical parameter for maintenance of bridges which have been designed with bearings. The bearings require replacement during the service life of the bridge and wide bridge superstructures with a large number of bearings potentially cannot be jacked using the current departmental jacking facilities. Transport and Main Roads’ current computer-controlled jacking system can operate a maximum of 20 jacks simultaneously and use of less than 20 jacks is preferable. For simply supported spans with a continuous deck slab, both sides of the headstock have to be jacked simultaneously with the synchronised jacking facility resulting in a maximum of 10 jacks per span.

Wider bridge superstructures that do not meet these criteria shall be divided and designed as separate superstructures. The minimum clear separation distance between structures shall be as noted in Sections 1.3.1 and 1.3.2

Due to the quick setting time for the epoxy used to seat the bearings, there is a short time period to replace a bearing and a requirement for a large number of trained skilled workers. Dividing the superstructure has the benefit of reducing the number skilled team members required, substantially reducing the closure time and ensuring a manageable jacking operation.
Refer Section 4.6.2 for further requirements for provision of jacking for bearing replacements.

1.4 **Stage construction and provision for future widening**

1.4.1 *Future widening*

a) Allowance shall be made for any future widening of bridges included in the design requirements. Couplers, ducts and other necessary details shall be provided and detailed on the drawings.

b) Breaking back of concrete to lap reinforcement is not permitted. Projecting exposed reinforcement is not permitted.

c) Wherever possible, the connections shall be detailed to minimise or eliminate the need for future modification of the bridge being designed. Details of the widening methodology, including outline drawings of the widening, the method of attachment, the loading code used and loading limits, including the design Serviceability Limit State (SLS) and Ultimate Limit State (ULS) forces allowed for in the design of the bridge, shall be included on any appropriate bridge drawings.

1.4.2 *Stage construction*

Details of minimum lane widths and minimum number of traffic lanes are in the road design criteria.

a) During the first stage of a bridge constructed by stage construction, the HLP 400 design load is not required, unless the first stage is 8 m wide or more; however, the completed bridge shall be designed for all stage loads, including HLP 400.

b) Permanent and / or temporary traffic barriers are required on the sides of the bridge. In one-lane operation, the traffic barrier shall be designed with due consideration of the traffic speed and distribution of vehicles.

c) Minimum lane widths and minimum number of traffic lanes are to be as detailed in Section 7 (Item S1) or elsewhere in the brief or Scope of Work and Technical Criteria (SWTC).

d) Where a longitudinal stitch pour is required to join reinforced concrete decks or other components subject to traffic movements or vibration, provision shall be made to ensure that stitch pour can be completed within a 48 hour period. During this period, provision for reducing or minimising the deflection, differential effect and vibration shall be made.

1.4.3 *Widening an existing bridge*

a) Refer Section 8.7 of the department’s *Drafting and Design Presentation Standards Manual* Volume 3 for required survey information to produce the design and drawings for bridge widening.

b) A bridge widening shall normally be done using the same cross-sectional profile of beams and decks or deck units as the original bridge, unless loading or hydraulic requirements require modifications.

c) When a bridge is widened, the new section of deck shall be made integral with the existing deck. A longitudinal joint in the roadway is not acceptable.

d) The existing bridge will have been designed to the current code of the time. Whilst it is desirable that the widened bridge fully conforms to AS 5100, where this is not reasonably practical or is uneconomic, the widened structure shall be designed to accommodate loading...
compatible with the original bridge and be equal in strength or structurally stronger than the existing bridge. For design traffic loads for widening existing bridges, refer to Section 3.2.3.

e) Footpath width shall desirably conform to AS 5100 requirements. For bridge rehabilitation, a narrower footpath may be considered after taking into account the expected remaining life of the structure, traffic, and cost benefit of the conforming width and practicality of strengthening. The minimum width of the footpath shall be 1.8 m. Any variation from AS 5100 shall only be permitted with the written acceptance of the Director (Structures Review and Standards). Design loading shall conform to AS 5100 and Chapter 6 of this document.

f) The footpath loads for an attached footpath shall be as per AS 5100. The addition of a footpath shall not significantly reduce the traffic load capacity of the bridge. However future demand of traffic on the bridge shall be reviewed and considered for the design.

g) Widening shall not reduce the structural stability or load capacity of the structure below the existing capacity of the bridge or culvert.

h) The expansion joint seals and Deck Wearing Surface (DWS) of the entire width of the bridge shall be replaced as part of the Works.

i) Where a longitudinal stitch pour is required to join reinforced concrete decks or other components subject to traffic movements or vibration, provision shall be made to ensure that stitch pour can be completed within a 48 hour period. During this period, provision for reducing or minimising the deflection, differential effect and vibration shall be made.

j) Condition assessment of the existing transverse stressing bars in existing deck unit bridge decks shall be undertaken, if these are to be extended for bridge widenings. Method of testing and assessment criteria shall be submitted to the Director (Structures Review and Standards) for acceptance prior to conducting the assessment.

1.4.4 Widening two bridges on separate carriageways

When a divided road is widened into the central median, the widened bridges shall remain separated to avoid the problems of an extra-wide deck and thermal movements. A minimum horizontal distance of 2.0 m shall be maintained between the two bridges for inspection and maintenance. Where this is not possible, the options shall be determined and referred to the Director (Structures Review and Standards) for acceptance.

1.4.5 Estimating residual life of existing bridge

Residual life is the remaining life of a structure, taking into account changes to the operating environment and its current condition.

1.4.5.1 Future operating environment

a) Factors that impact the operating environment are:
   - operating condition of the road, including usage as heavy vehicle route
   - hydraulics
   - location of widening on heavy vehicle route and the residual life of the original structure, and
   - difference between local authority roads, service roads and departmental roads.
b) Changes in land usage, from rural to urban for example, will significantly change the runoff in streams. Consideration shall be given in future land usage in determining if an existing structure has adequate waterway area, needs to have the waterway increased or needs to be replaced by a new bridge or culvert.

c) For design loads applicable to widened bridges refer to Section 3.2.3.

1.4.5.2 Estimating structural residual life

a) Bridges are designed for a nominal design life of 100 years. Design life for culverts and other small drainage structures are as listed in Chapter 17 (prior to 2004, the nominal design life for culverts was 50 years).

b) The nominal residual life of the structure is the difference between the nominal design life and the age of the structure.

c) The residual structural life of the structure shall be determined. The residual structural life shall consider if initiation or propagation of deterioration has commenced, and whether current or future load increases or changes in environmental and exposure conditions will increase the rate of deterioration. Testing shall be done to determine whether the initiation or propagation phases are relevant to the structure.

d) The need to rehabilitate existing structures will either:
   • be defined elsewhere in the Scope of Works and Technical Criteria (SWTC), or
   • be advised on completion of condition surveys and the assessment and calculation of the estimated operational residual life.

1.4.6 Working with asbestos in bridge rehabilitation works

1.4.6.1 Identification of the asbestos

Designers shall investigate whether any permanent asbestos items have been used in an existing bridge prior to preparing the rehabilitation proposals. This investigation shall identify the locations and the type of the asbestos at the workplace.

Requirements for working with asbestos in bridge rehabilitation works should be undertaken in accordance with the department’s Engineering and Technology (E&T) Asbestos Implementation Guideline which details the specific procedure and roles and responsibilities to be applied by E&T for the management of asbestos risk.

Asbestos components shall be tested by electron microscopy with dispersive X-rays or equivalent to identify asbestos fibres as defined in the Work Health and Safety Act 2011. Identification of fibres as asbestos using electron microscopy techniques can be undertaken in consultation with Queensland University of Technology (QUT). If asbestos is identified, a written asbestos management plan shall be developed by a qualified person in accordance with Work Health and Safety Regulation 2011.

Asbestos can occur in the following locations of existing bridges:

- permanent formwork for insitu deck slabs with girders including separated deck units
- suspended services (for example drainage pipes, water mains)
- cast-in services (for example conduits and drainage fittings)
- buried services including ducts and pits
• electrical and communication pits, and
• miscellaneous packing and sealing products.

1.4.6.2 Asbestos removal and asbestos related works

Management and removal of asbestos shall be in accordance with MRTS96 Management and Removal of Asbestos.

Asbestos removal must only be done with specific care to minimise asbestos fibres becoming airborne. The following WHSQ guidelines shall be followed:

• Safe Work Procedures techniques
• How to Safely Remove Asbestos Code of Practice 2011
• How to Manage and Control Asbestos in the Workplace Code of Practice 2011
• Work Health and Safety Regulation 2011, and

Asbestos removal shall be carried out by an appropriately licensed asbestos removal contractor, unless exempted by the Work Health and Safety Regulation 2011 for the size and class of the proposed asbestos work. The type of licence required for transport and disposal of asbestos waste shall be in accordance with the Work Health and Safety Regulation 2011.

Licensed asbestos removalists must ensure that asbestos waste is disposed to an authorised site in accordance with the guidelines provided in the WHSQ Code of Practice How to Safely Remove Asbestos.

1.4.6.3 Clearance certificate

On completion of the licensed asbestos removal works, a clearance inspection shall be carried out by a licensed asbestos assessor or a competent person and a clearance certificate shall be issued in accordance with WHSQ guidelines to verify that the work place is safe for normal use.

All documentation must be given to the Asbestos Controller for uploading to the Central Asbestos Register.

1.5 Quality assurance in design documentation

1.5.1 Structural design objectives

a) Structural design shall conform to a high level of technical competence and shall be based on proven methods, materials and technology. All structures shall be designed in accordance with good engineering practice, relevant codes and incorporate safety in design principles. All structures must have an attractive appearance appropriate to their general surroundings and any adjacent structures. The design shall be practical and cost-effective to construct and maintain.

b) All bridges and other structures shall be:

• designed and / or supervised by an experienced structural engineer who is a Registered Professional Engineer of Queensland (RPEQ)
Chapter 1: Design requirements for bridges

- design checked by an appropriately experienced engineer who is an RPEQ; the engineer who undertakes the check shall be different to the Designer, and shall carry out independent calculations, and

- in all instances the design checker shall be nominated from a team that is not involved in the design.

Depending on the complexity of the design, the design checker may be either:

a) from the same office of the same firm

b) from a different office of the same firm, or

c) from a different firm or as defined in the Design Brief.

1.5.2 Conforming product, alternative product and innovation

a) ‘Conforming’ materials and products are all materials and products detailed in the department’s Technical Specifications or as amended by the project design brief. Any other material or product is deemed to be ‘non-conforming’ and shall only be used on bridges with the prior written acceptance of the Director (Structures Review and Standards).

b) Transport and Main Roads recognises the need for innovation in design, materials and products. An innovative product shall be equivalent to or exceed existing design, materials or products in all aspects of performance and be robust, that is, able to withstand normal and accidental loads in use without significant damage, and durable when exposed to the environment with an appropriate service life.

c) Innovations in structural design shall only be adopted for construction after appropriate testing and validation, and acceptance in terms of safety, durability, future performance, constructability and maintenance by the department. It is suggested innovation is best undertaken outside a Contract. Experience has shown that acceptance of innovative design, materials and products may take up to three years and involve extensive testing and development of specifications.

d) Transport and Main Roads Specifications are conscious decisions of the department’s structural engineers to provide long service life and minimum whole-of-life cost.

1.5.3 Review of drawings and scheme documents

a) The minimum scheme documents shall comprise the Design Report, Supplementary Specifications (if applicable) and MRTS Annexures.

b) The project drawings and scheme documents shall be reviewed and accepted in terms of safety, durability, future performance, constructability and maintenance by the department’s Structures directorate.

c) Drawings shall be submitted at preliminary design (15%), 50% substantial completion (unchecked drawings), 85% complete (checked drawings) and for 100% design for final acceptance.

d) The preliminary design submission (15%) shall involve a meeting and presentation of drawings. The drawings shall include all typical project details. The design shall not proceed until all issues are resolved.
e) Transport and Main Roads will provide comments that the Designer must consider, and these shall be included in the design. If any comments are not acceptable to the Designer, reasons shall be discussed with the department. A final position shall be reached, and the final version shall be subject to acceptance by the department before being adopted.

1.6 Bridge design report

1.6.1 Phases of report

A design report shall contain the following information, and shall be delivered at appropriate stages in the design development.

a) The first four phases of design development are intended to manage information transfer, change requests and relevant acceptances; hence they shall be as concise as possible, and the issues requiring resolution shall be suitably highlighted.

b) Where practical, bridge information shall be conveyed by drawings and sketches in preference to text.

c) Design non-conformances submitted for acceptance shall be suitably tabulated.

d) The design report shall be accompanied by the department’s commissioning letter or design brief, including attachments. Subsequent design phase reports shall specifically note any of the conditions in the SWTC which are not being met, or changes requested.

e) When a project contains multiple bridges / structures, individual design reports shall be prepared for each bridge / structure.

1.6.2 Fixing report – bridge location determined

The fixing report is issued when sufficient information has been gathered and the exact location of the bridge can be determined in relation to the road geometry, waterway analysis, required clearances and any other restraints. In general, the bridge spans will be determined at this stage.

Consideration shall be given to minimise the number of bridge bearings to facilitate jacking for bearing replacement. The use of separate superstructures shall also be considered (refer Section 1.3.1).

General arrangement drawings of the bridge shall be provided with the fixing report.

1.6.3 15% complete design report

a) At the 15% complete stage, all preliminary investigations have been completed, including structural design, hydraulics, geotechnical investigations, clearances and other requirements of relevant authorities. The spans, articulation, substructure and superstructure type have been selected, as have preliminary founding levels. Traffic barrier performance level, drainage, lighting and other service requirements have been agreed.

b) Departures from the department’s design brief, SWTC and departmental Technical Specifications shall be listed in the design report for Transport and Main Roads’ review.

c) The general details shall be shown on draft drawings that include:

- general arrangement
- exposure classifications, concrete cover and concrete grade for each element
- abutment and pier drawings, and
• a superstructure cross-section.

d) It is expected that the major design parameters will not change during detailed design and drafting.
e) If major changes are subsequently made, a supplementary report shall be sent to Transport and Main Roads as soon as practical.

1.6.4 50% complete design report

50% complete stage design report shall be submitted for Transport and Main Roads review. This report shall include minimum of:

• proposed design changes if any from 15% design submission
• geotechnical and hydraulic report
• durability report including thermal modelling results and recommendations if applicable
• safety in design report.

50% detail design drawings shall be included.

1.6.5 85% complete design report

a) At the 85% complete stage, the design is effectively complete and a complete set of draft scheme documents and drawings shall be available for review by the department.

b) The design report shall highlight any non-conformance to the design brief, SWTC or any subsequent agreements or instructions issued subsequent to earlier design reports.

1.6.6 Final design report

The final design report shall contain all the previous stage reports including final drawings, cost estimates, steel schedules, Electronic Project Model (EPM) and all the archival material required, as set out in the department’s bridge design report template.

It lists all requests for changes to the design standards and technical specifications, and a tabulation of the matters for resolution.

The final report contains all relevant information and shall highlight any non-standard construction materials, components or methods requiring action by the construction Contractor, or by subsequent asset management processes (inspection and maintenance).

The design report shall include but not be limited to the following:

• design codes including date of publications and (any) amendments
• date of referenced Transport and Main Roads Design Criteria for Bridges and Other Structures
• statement for each item in Matters for Resolution by Authority, AS 5100.1 Appendix A
• a statement of design loads outlined in Clause 1.2 of AS 5100.2
• a statement to confirm the design model and analysis approach used
• calculation of the barrier design loads – AS 5100.1 Appendix B – adjusted for minimum value specified by the department if applicable
• other referenced documents
• design criteria from other stakeholders / authorities
• the design methodology, design assumptions, serviceability and ultimate loads
• statement of design life of the bridge and each sub-elements
• other controls / limits / restrictions (for example shipping clearance, traffic clearance)
• construction methodology (for example, Super T-Girders composite at 100 days)
• durability
• robustness of design
• ‘safety in design’ considerations for construction, inspection, maintenance and operation (refer Section 3.16)
• design data for input into Bridge Information System, and
• Structures Inspection Manual.

The report shall demonstrate conformance to the project design brief. Any proposed variations from the design brief or SWTC shall be discussed in terms of cost, safety, durability, future performance, constructability and maintenance. Variations shall be submitted for acceptance by the Director (Structures Review and Standards).

After approval, the variations may be incorporated into the design. All approved design variations shall be documented in the Design Report.

The final Design Report shall be submitted as part of the final scheme submission for Transport and Main Roads approval. For Alliance / Early Contractor Involvement / Design and Construct type projects, the Design Report shall be approved by the department prior to commencing the construction.

1.7 Design certification

a) A geotechnical design report, RPEQ-certified by an experienced geotechnical assessor, shall be included in the final Design Report for each bridge.

b) A structural design report, RPEQ-certified by an experienced structural engineer, shall be included in the final Design Report for each bridge.

c) Design certification is required for each retaining structure.

1.8 Innovative materials and components

Preparation of inspection and maintenance procedures for innovative materials and components shall be as follows:

a) The Designer shall assess all materials, coatings and components of the design to ensure they conform to the standard materials and procedures for in-service inspection and maintenance in the department’s Structures Inspection Manual.

b) Novel and innovative designs, not covered by the standard inspection and maintenance procedures, shall have relevant procedures and information prepared and submitted with the final design report.
c) Where a procedure is required, it shall include the following details:

- inspection frequency, based on the risks which develop as the material / component degrades over time
- any special provisions for inspection access
- any tools, equipment, measurements, test procedures needed to assess the material / component in situ
- method of repair or replacement of a component and any diagrams necessary for safe working
- any routine maintenance required including cleaning, recoating, and so on
- a practical method for inspection and replacement of bridge bearings, with jacking points and loads shown on the drawings, and
- a detailed schedule for cleaning, preparation and recoating for any bridge with paint or similar protective coating. Repainting must be practical without significant interruption to traffic flow.

1.9 ‘As Constructed’ drawings and construction handover report

Refer MRTS50 Specific Quality System Requirements and Drafting Design Presentation Standard Manual, Volume 3, Chapter 1, Introduction.
2 Bridge aesthetics

2.1 General

Following bridge aesthetic aspects shall be considered in design:

a) All structures must present smooth, clean lines and bridges shall have a minimum structural depth consistent with their spans and method of construction.

b) The design of bridges shall address the slenderness aspects of the structure and consider the effects of the parapets and all other elements of the structure in the determination of the apparent visual slenderness. Dominant horizontal lines shall be smooth and continuous.

c) Bridge proportions shall represent spanning and supporting requirements, and shall respond to the context of the individual bridge localities.

d) Length of spans shall be maximised where practical, within the context of the necessary bridge length.

e) Bridge structural elements such as piers, headstocks (including leading edges), sill beams and abutments shall be aesthetically integrated.

f) The bridge deck, kerb and barriers shall extend beyond the deck units by a minimum of 100 mm with 19 x 19 mm triangular drip groove to prevent water staining of the units and for aesthetics.

g) Columns with only two lines of symmetry (that is rectangular or elliptical) must have the longest edge transverse to the deck structure.

h) All superstructure elements must follow design vertical and horizontal profiles.

i) Spill-through abutments shall have a batter slope no steeper than 1:1.5.

j) On all exposed concrete surfaces on structures:
   - the finishes and colour must be uniform, and
   - tie holes must be aligned in a uniform pattern, and subsequently filled with mortar to achieve a smooth uniform coloured finish.

k) All structures must be of uniform colour and surface finish. Repair of defects and patching must match the appearance of the remainder of the surface.

l) Roads and Maritime Services (RMS) Bridge Aesthetics: Design Guidelines to Improve the Appearance of Bridges in NSW shall be used as a guide to the basic minimum aesthetics standards.

2.2 Anti-graffiti coating

a) With the exception of rural areas, the accessible surfaces of all structures, noise-attenuating structures, walls, barriers, doors, louvres and other features must be treated with non-sacrificial anti-graffiti coating in accordance with the following requirements:

   i. Anti-graffiti coating shall not be applied on galvanised steelworks.

   ii. The anti-graffiti coatings must match the adjacent surface, and the colour appearance of the structure must not be altered by the application of the coating.
iii. Treatment of the surfaces must be to a minimum height of 3 m above the surrounding reinstated ground levels or any accessible footholds.

iv. Where part of an element of a structure requires treatment on the basis of the height criteria in Section 2.2 a) iii., then the whole element must be treated, and

v. To protect surfaces prior to applying the permanent anti-graffiti coating, the Designer and Contractor may use a sacrificial coating, provided that it in no way interferes with the adhesion of the permanent coating.

b) The design of all structures, tunnel linings, noise-attenuating structures, walls, barriers, doors, louvres and other features must consider and address the aesthetic impact of anti-graffiti coatings on the element, the structure and the family of structures.

c) Subject to Transport and Main Roads' regional requirements, it is acceptable to use water-based paint to conceal graffiti; however, the paint shall match the colour of the adjacent surface, and appearance of the structure must not be altered by the application of the coating.
3 Bridge functional requirements

3.1 Traffic capacity

3.1.1 Number of lanes and bridge carriageway width

a) In general, the bridge will have the same number of lanes as the adjacent roadway. Bridges near intersections, or forming part of interchanges, may require additional lanes to achieve safe design weaving lengths for adjacent entry and exit lanes.

b) The lane layout shall be determined by the road Designer prior to commencing bridge design, and the required lane geometry shall form part of the Bridge Design Brief.

c) Where future widening of a bridge is planned, and construction of the additional lanes will be expensive due to high traffic volumes on the associated roadways, the original design shall consider whether the widened bridge would be more economically and safely built in the first stage. The allowance for future widening may include substructure alone (ready for superstructure erection at a future date) or the complete structure.

d) For minimum bridge carriageway widths, refer to Figure 3.1.1 and Tables 3.1.1(a) to (e).

| *AADT: Average Annual Daily Traffic*
3.1.2 Clearances and shoulder width

3.1.2.1 Long bridges

a) The design shall include an assessment of the width required for safe inspection and maintenance activities while maintaining traffic flow at reduced speed.

b) Expanding on the requirements in RPDM 2nd Edition, the width of all bridges including long bridges, shall be increased to include:
   - bicycle lanes where they are required on the approach roads, or
   - adequate safety for cyclists where they are expected to ride on the shoulders of the approach roads.

c) The Designer’s attention is also drawn to the RPDM 2nd Edition regarding stopping sight distances.

3.1.2.2 Spans for overbridges

a) A bridge spanning a major roadway shall provide full clearance and shoulder widths on the road beneath. Allowance for the longitudinal drainage, services and maintenance operations shall be considered and provided where necessary.

b) Allowance for future widening of the road beneath shall be included if this is planned or likely in the next 100 years.

3.1.2.3 Clearances in design brief

The design brief or project SWTC shall specify clearances. If not, the Designer must consult with Transport and Main Roads prior to commencing detailed design.

3.1.2.4 Height clearances for bridges over roads

a) The minimum vertical clearances for vehicular bridges over roads are specified in Table 3.1.2.4.

<table>
<thead>
<tr>
<th>Description of road beneath bridge</th>
<th>Preferred minimum</th>
<th>Absolute minimum</th>
</tr>
</thead>
<tbody>
<tr>
<td>Very high clearance routes (where no suitable convenient alternative is available)</td>
<td>6.5 m[^1,^2]</td>
<td>6.0 m[^3]</td>
</tr>
<tr>
<td>Highways and motorways</td>
<td>6.0 m[^2]</td>
<td>5.5 m[^2,^3]</td>
</tr>
<tr>
<td>Declared roads</td>
<td>5.5 m[^2]</td>
<td>5.5 m[^2]</td>
</tr>
<tr>
<td>Other arterial and main roads</td>
<td>5.5 m[^2]</td>
<td>5.5 m[^2]</td>
</tr>
<tr>
<td>Other local authority roads</td>
<td>5.3 m[^2]</td>
<td>4.8 m[^4]</td>
</tr>
</tbody>
</table>

[^1]: Generally either 6.5 m clearance or a suitable convenient alternative route (for example via entry and exit ramps or heavy vehicle bypass roads) should be available on the motorways and highways that are the major through freight routes (for example Port of Brisbane, Gateway, Logan and much of the Pacific Motorways, and most highways).

[^2]: Heights provide 300 mm resurfacing or pavement strengthening to the major roads, and 100 mm to ‘Other local authority roads’.
³ The absolute minimum vertical clearance for ‘Very high clearance route’ and ‘Highways and motorways’ has no allowances for overlays. It should only be adopted where a pavement with a long design life has been used: for example HILI (High Intervention, Low Intensity) pavements, pavements with a 40 years design life.

⁴ Although the legal height of livestock and vehicle carrying vehicles is 4.6 m, to reduce the risk of accidental impact and damage, the minimum clearance required is 4.8 m.

b) The minimum clearance for footbridges over very high clearance routes is 6.8 m (6.5 m vehicular bridge clearance plus 0.3 m) and on declared main roads is 6.5 m. For footbridges over local authority roads, the clearance shall conform to the local authority requirement, subject to departmental acceptance of these values. For local authority roads, footbridges must have 1 m greater clearance than any adjacent road bridge structures on the road link but maximum clearance is 6.5 m.

c) For the existing bridges with a height clearance less than in Table 3.1.2.4, the existing clearance (as measured on site) is to be maintained. This includes the provision of additional lanes under these bridges.

d) For additional requirements for existing bridges or new bridges to be designed with a height clearance less that in Table 3.1.2.4 with the approval of Transport and Main Roads’ Director (Structures Review and Standards), refer to Chapter 7 Item 44.

e) Any special clearances shall be in accordance with Chapter 7 (Item S2).

3.1.3 Geometry, design speed

a) Special consideration shall be given to any bridge which does not conform to the design speed of the rest of the road link. Sudden increase in curvature on a bridge or bridge approach can significantly increase the risk of vehicle roll-over that could result in a vehicle going over the edge of a bridge. If the geometry cannot conform to adjacent speed characteristics (which may be above posted speed limits), then additional warning signage and increased bridge barrier capability must be provided.

b) For bridges on interchanges, the design speed shall not be less than the adjacent through road design speed, less 20 km/h (that is, for a road with a design speed of 120 km/h and posted speed limit of 100 km/h, an interchange bridge shall have a minimum design speed of 100 km/h and a posted speed limit of 80 km/h).

c) The Designer’s attention is also drawn to stopping sight distance requirements.

3.2 Load capacity – freight efficiency

3.2.1 Design loads and construction sequence

The design loads and any construction sequence limitations shall be shown on the project drawings and specifications for all bridges in accordance with AS 5100 Bridge Design.

3.2.2 Design traffic loads for new bridges

a) The design traffic live loads for new bridges are SM1600, W80, A160 and HLP 400 in accordance with AS 5100. Refer to Chapter 6 “Additional Requirements to AS 5100 Bridge Code” for specific design requirement for placement of Heavy Load Platform (HLP) loads.

Refer Section 3.2.8 for design traffic loads for busway bridges.
b) These design loads apply to all new road bridges on declared main roads, except in unusual circumstances that have been accepted in writing by the Director (Structures Review and Standards).

c) These conditions shall also apply to any overbridge across a declared main road which is likely to be travelled by a HLP which cannot fit beneath it and is likely to go across the overbridge.

### 3.2.3 Design traffic loads for widening / strengthening an existing bridge

The cost of widening / strengthening should be compared against the cost of a bridge replacement. If a new bridge to current loads is more economic, a new bridge should be constructed.

The design lane, excluding HLP, shall comply with AS 5100. HLP position shall comply with Chapter 6 of this document for additional requirements to AS 5100.

Other loading design parameters shall be as follows:

- Load factors for dead loads and superimposed loads: As per AS 5100
- Ultimate load factor for traffic loads (excluding HLP): 2.0
- Ultimate load factor for HLP, at speed: As per AS 5100
- Dynamic load allowance:
  - for cranes and AB triple, AAB quad, HML semi, at speed: 0.4
  - Vehicles specified in AS 5100, at speed: As per AS 5100
  - Vehicles at crawl: Zero
- Accompanying lane factors: As per AS 5100
- Other parameter: As per AS 5100

#### 3.2.3.1 Design traffic loads for simply supported spans of less than 50 m

Design traffic loads for simply supported spans of less than 50 m shall be as shown in the Table 3.2.3.1 and Figure 3.2.3.1 shows the details of 6 axle semi, AB Triple and AAB Quad.
Table 3.2.3.1 – Design traffic loads for simply supported spans of less than 50 m

* Axle Spacing

---

SUPERSEDED
3.2.3.2 Design traffic loads for simply supported spans over 50 m and continuous spans

Special criteria apply. Design must consider worst effect due to 6 axle semi, AB triple or AAB quad and design vehicles.

Additional criteria:

1. Maximum spacing between axle groups can vary between 4.4 m and 6.0 m for continuous bridges to create the worst load effect.
2. Minimum spacing between following vehicles is 3.0 m for stationary and 6.0 m when moving. Maximum spacing is the dimension to create the worst load effect considering pattern loading of spans.

3.2.3.3 Design traffic loads for local authority bridges and culverts

The load rating of a local authority bridge or local authority culvert shall be as specified by the local authority but not less than H20-S16.

3.2.4 Design traffic loads for damaged bridges

For bridges damaged in service, the damaged section shall be reinstated to the design traffic loads existing prior to damage. If the superstructure is required to be replaced, the new superstructure shall be designed to the criteria for new bridges if possible. If this cannot be obtained, the design loading shall not be less than T44, A14 and HLP 320.

3.2.5 Heavy Load Platforms (HLPs)

a) HLPs represent actual configuration of vehicles that travel on the road network, not design simplifications.

b) On road projects associated with major infrastructure (mines, power stations and so on), there may be a requirement for a heavier HLP in bridge design. Designers shall consult the relevant authorities before detailed design commences. Typically, a HLP can “safely” carry much higher loads (up to 50 tonnes / axle) than normally allowed on bridges (25 tonnes / axle).

3.2.6 Abnormal loads

Any requirements for abnormal loads shall be defined in accordance with Chapter 7 (Item S2).

3.2.7 Special conditions for footbridges

For the design of a standalone footbridge, lateral loads (AS 5100.2, Clause 9) are a critical load case. For new structures the minimum lateral load is 500 kN.

For footbridges over waterways and navigable channels, ‘ship’ / navigational vessel impact shall be taken into account. AS 5100 does not address ship impact; however, Transport and Main Roads Design Criteria for Bridges and Other Structures covers this issue in Chapter 7.

3.2.8 Design traffic loads for busway bridges

The bridges that are used only for busway traffic shall be designed for the following traffic loads; however, in the case of bridges used for both busway traffic and general road traffic, the whole bridge shall be designed for road traffic loads. Refer Section 3.2.2 for design traffic loads for road traffic bridges.
Busway traffic loads

Busway bridges shall be designed for T44 truck load. One truck load is applied per lane. For continuous bridges, one T44 truck load per span per lane shall be considered in the design. T44 trucks shall be located on the structural model to get worst action effect. For spans greater than 10 m, bridges shall be designed for L44 lane load in addition to T44 truck loads. T44 truck load and L44 lane load shall be in accordance with AS 5100.7.

In addition to this, all busway bridges shall be designed for capacity to carry one 48 t crane load placed anywhere on the bridge deck. A 48 t crane configuration is shown in Figure 3.2.8.

**Figure 3.2.8 – 48 t crane configuration**

For all structural elements for which the critical load is a wheel load, an additional load effect consisting of a 70 kN load (W7 wheel load) over a contact area of 500 x 200 mm shall be considered.

Dynamic load allowance ($\alpha$) for W7, T44 and L44 traffic load shall be 0.4. Serviceability and ultimate limit state load factors for W7, T44 and L44 shall be 1.0 and 2.0 respectively.

Dynamic load allowance ($\alpha$) for 48 t crane load shall be 0.4. Serviceability load factor and ultimate load factor for 48 t crane shall be 1.0 and 1.8 respectively.

**Centrifugal forces**

Centrifugal forces on busway bridges shall be calculated similar to AS 5100.2 except that M1600 vertical load shall be substituted from T44 (for calculation of $W_c$ in AS 5100.2). Load factor for serviceability limit state shall be 1.0 and for ultimate limit state 1.8. No dynamic load allowance is to be included.

**Braking forces**

Braking load for busway bridges shall be calculated similar to AS 5100.2 except that M1600 vertical load shall be substituted from T44 (for calculation of $W_{BS}$ & $W_{BM}$ in AS 5100.2). Load factor for serviceability limit state shall be 1.0 and for ultimate limit state 1.8. No dynamic load allowance is to be included.

**Fatigue load effects**

Fatigue design load effect shall be determined from the effect of single W7 wheel, T44 or L44 load. Load factor of 1.0 shall be used and load effect shall be increased by the dynamic load allowance ($\alpha$). The number of fatigue stress cycles to be used for the calculation of fatigue capacity shall be in accordance with Table 3.2.8.
Table 3.2.8 – Number of stress cycles for fatigue design

<table>
<thead>
<tr>
<th>Fatigue design traffic load</th>
<th>Number of fatigue cycles</th>
</tr>
</thead>
<tbody>
<tr>
<td>W7 wheel load</td>
<td>2 000 000</td>
</tr>
<tr>
<td>T44 truck load</td>
<td>500 000</td>
</tr>
<tr>
<td>L44 lane load</td>
<td>100 000</td>
</tr>
</tbody>
</table>

The number of stress cycles for fatigue design in Table 3.2.8 is based on AS 5100.7: Table A3 for road functional Class 6 for urban busways and for functional class 1 for rural busways.

3.2.9 Design traffic loads for light rail passenger transit bridges

Currently AS 5100.2 (2004) does not specify light rail loading design requirements, although this is proposed to be included in the next revision to AS 5100.2. In the interim, the following light rail traffic design loads shall be used for the design of bridges carrying light rail traffic.

Other requirements of design criteria for light rail loading structures will be aligned when the next revision to AS 5100 is released.

Light rail load

Light rail design load shall be 150 LA, based on 50% of the 300 LA rail load as detailed in AS 5100.2 Clause 8 for railway traffic loading.

Transport and Main roads light rail loading criteria will be limited to Light Rail Transit (LRT) at this stage and not required to cover cane rail bridges. Therefore, leading axle (locomotive) will be omitted and there will be no limit on number of axles to allow for longer connected trains or queuing.

The 150 LA light rail group shall consist of 150 kN axle loads in groups of four with axle spacing of 1.7 m, 1.1 m and 1.7 m, as shown in Figure 3.2.9(a). The spacing between the centres of each axle groups shall vary between 12 m and 20 m to give maximum effect in the member under consideration, as shown in Figure 3.2.9(b). The position of loads and number of axle groups shall be selected so as to give maximum load effects in the member under consideration.

Figure 3.2.9(a) – 150 LA light rail traffic loads – axle loads
3.3 Load capacity – environmental and construction loads

3.3.1 Mining subsidence

a) Mining is one of the most common activities that can have a considerable impact on the design of a bridge. Assessment of mining impacts requires close liaison with the relevant statutory authority and the mining company, if mining has occurred or is already in progress.

b) Maps of designated mine subsidence areas are produced by relevant state authorities. Bridges constructed in those areas must be designed for anticipated ground movements resulting from past and future mining activities.

c) The design parameters for ground movements are usually prepared by the mine subsidence authority using geotechnical models, and include vertical displacement and the orientation and degree of the ground slope. The ground slope results from the transition from the original ground levels to the subsided ground levels. It moves as a 'wave' through an area as mining progresses, and hence differential movements and rotations may occur over the length of the bridge.

d) The need to accommodate mine subsidence movements may require but not limited to the following:

- the use of simply supported spans as opposed to continuous spans to accommodate rotations
- additional fixings or restraints to ensure spans do not move enough to fall off their bearings / supports
- the provision of measures to accommodate movements at abutments by using precast curtain walls to facilitate movements
- the use of bearings that will allow free movement at piers and abutments; for example, the use of guided slide pot bearings with removable side guides will allow movements without damaging the bearings
- the use of bedding material under spread footings that will allow rotations to occur without damaging the substructure, and / or
- special considerations to remove part of the bridge to accommodate movements; for example, provisions to remove a span on a pedestrian bridge when the ground movements cannot be accommodated by the structure.
e) Detailed procedures of action required in the event of mine subsidence being imminent must be shown on the drawings, together with the design parameters used.

f) Confirmation in writing must be obtained from the mine subsidence authority that parameters used in the design are still appropriate for the actual movements being recorded.

g) The design report must include full details of provisions for mine subsidence and any advice (including the confirmation mentioned above) from the mine subsidence authority.

3.4 Hydraulic investigation, flood loadings and levels

The department’s Road Drainage Manual (RDM) is currently being updated. One aspect of the update is to do with climate change. From the most recent and relevant publications on climate change the manual will conclude:

1. there is no definitive data to conclude any increase in rainfall intensity for storms up to a 100 year Annual Recurrence Interval (ARI) event

2. whilst changes in average rainfall are still relatively uncertain, a number of studies suggest increases in the intensity of the heaviest rainfall events; some freeboard to probable maximum flood levels to 2100 is warranted, and

3. sea level rises of 600 mm are predicted to 2100.

ARI is defined in the RDM as the average or expected value of the period between exceedances of a design discharge. It should not be confused with the design life of a structure.

Storm tides, Highest Astronomical Tide (HAT) and climate change induced sea level rise are only applicable in coastal areas.

3.4.1 Hydraulic investigation

The hydraulic investigation shall be undertaken by one of the following three options.

Option 1

The Consultant must perform a hydraulic study for each bridge including:

a) serviceability effects of afflux and increased stream velocity on adjacent properties and the stability of the adjacent road embankment – all floods up to the 100 year ARI flood

b) flood immunity in accordance with the RDM, and

c) ultimate limit state of bridges–2000 year ARI flood. The overtopping event shall also be considered if this is less than the 2000 years ARI flood. The overtopping event will typically cause critical conditions in terms of peak velocities.

The study shall be carried out to the requirements of the department’s Road Drainage Manual, Hydraulic Guidelines for Bridge Design Projects and Storm Tide – Issues for Design of Road Infrastructure in Coastal Areas (where applicable). The hydraulic investigation report should be submitted to Transport and Main Roads’ Director (Hydraulics and Flooding) for review and acceptance.
Option 2
The hydraulic investigation report shall be supplied to the Consultant.

Option 3
Hydraulics investigation is not required in this project.

3.4.2 Minimum hydraulic forces on bridges

a) The minimum hydraulic force on a bridge pier shall be 75 kN per pier. The minimum stream velocity for calculating hydraulic forces in accordance with AS 5100 shall be 2.0 m/s.

The minimum stream velocity criteria is to ensure robust structure but not to be used for estimation of scour or provision of scour protections.

b) Minimum debris depth:
   i. where flood forces act on superstructure, the depth of debris mat shall be the greater of 3.0 m or the structural depth of the superstructure in elevation (solid) plus 1.5 m
   ii. where flood forces act on substructure only, the depth of debris mat shall be 3.0 m minimum.

Refer Australian Rainfall & Runoff Project 11 – Blockage of Hydraulic Structures, Stage 2 Report, PII/S2/021 February 2013 for further information on blockage of hydraulic structures due to urban debris.

c) In locations subject to tidal inundation or backwater inundation, flood forces may be applied on either side of the bridge structure.

3.5 Construction loads

3.5.1 Incrementally launched prestressed concrete bridges

When designing incrementally launched prestressed concrete bridges, the standards detailed in Table 3.5.1 must apply during the launching stage.

Table 3.5.1 – Construction loads: prestressed concrete bridge launching

<table>

3.7 Sustainability

3.7.1 Design life – new bridges

a) All bridgeworks and retaining walls must be designed and detailed to ensure an operational design life of 100 years, without major maintenance requirements. Painting of steel structures is considered normal maintenance. Repainting must not cause significant traffic disruption.

b) Design life for sub-elements of bridges which are less than 100 years and design life of other related structures are as follows:

- Expansion joints 40 years
- Rubbers in expansion joints 20 years
- Drainage systems (replaceable elements only) 50 years
- Steel bridge traffic barrier, safety screens and fencing 50 years
- Light poles and signs on side of bridge 40 years
- Bearings with provision for simple replacement 40 years
- Bearings with no practical means of replacement 100 years

(For this application, stainless steel pot bearing is mandatory)
• Noise barriers – refer Transport and Main Roads Technical Specification MRTS15 Noise Fences
• Abutment and pier scour protections 50 years
• Median slabs 50 years

c) The design life shall be interpreted such that there is a 95% probability that, during the design life, the structure or element:
• will not require major maintenance or replacement of elements
• will be fully functional
• will require minimal maintenance, and
• will blend and harmonise with the existing surrounds and planned landscaping.

3.7.2 Design life for drainage structures
Refer Chapter 17 for design life for drainage structures.

3.7.3 Design life – remedial works
Design life for remedial works shall be approved by the Director (Structures Review and Standards) prior to the commencement of the design.

3.8 Durability – bridges

3.8.1 Steelwork
All steelwork shall be hot dip galvanised to AS/NZS 4680 Hot-dip galvanized (zinc) coatings on fabricated ferrous articles, with a minimum coating in accordance with Table 1 of AS/NZS 4680. Material with a silicon and phosphorous content less than the following will need to be whip blasted to create a surface profile prior to galvanising. These requirements shall be included on the drawings.

\[ \%Si < 0.04\% \]
\[ \%Si + (2.5 \times \%P) < 0.09\% \]
Adequate vent holes for galvanising process shall be detailed and shown on the drawings.

3.8.2 Fitments material
a) The durability of the materials used for fitments (includes anchor bolts, traffic barrier connections, anchorage points, bearing bolts, machine screws and so on) must be considered in light of the exposure conditions. In marine conditions, the use of Grade 316 (A4) stainless steel fitments will reduce long-term maintenance costs and offset higher initial costs. The cost of replacement may be disproportionately high compared to the extra cost of the more durable material.

b) Fitments shall be hot dipped galvanised cast-in ferrules or sockets; however, stainless steel cast-in ferrules or sockets shall be used in marine or corrosive environments.
3.8.3 Painted steel structures

3.8.3.1 General

a) Painting as the primary corrosion protection will only be accepted when hot dip galvanising is not practical or cost-effective.

b) Paint systems shall be selected on the basis of the longest practical service life before recoating. Recoating in the field must be practical, without the need to grit blast to remove the original paint if sound.

c) Structures over roadways shall be detailed with appropriate access platforms, and so on, which will allow easy inspection and repainting, and clearances shall be provided so that traffic is not significantly interrupted during repainting. Access must be practical during daylight hours.

d) Surface coatings require the analysis of whole-of-life costing for inspection and repainting, and the cost of road closures necessary for painting shall be included. Night closures must consider dew point temperatures and paint sensitivity to moisture.

e) Duplex coatings may be required to achieve the design life and reduce / remove the need for repainting.

f) Prior approval shall be obtained from the Director (Structures Review and Standards) for the painting system.

3.8.3.2 Protective coatings – assumed life for costing analysis

a) Galvanising and proper careful detailing can give a ‘maintenance free’ life of 50 to 70 years. At that stage, once the galvanising has weathered away, painting will be required.

b) Shop painting and proper careful detailing shall give a life to first repaint of up to 30 years. Field-applied coatings, if done before full breakdown of initial paint system, may be assumed to last up to 15 years.

3.8.3.3 Detailing for durability

When detailing a structure to be painted for durability:

a) In non-galvanised painted steel structures, welded joints shall be used where practicable in preference to bolted joints to reduce corrosion risk.

Bolts are better than weld for fatigue design; however, Transport and Main Roads prefers welded connections if a paint system (not hot dipped galvanising) is used for corrosion protection of steelwork. The reason is that the design life of paint system on steelwork is less than hot dipped galvanising. When the paint system reaches the end of its design life, it needs to be repainted. The process of removing existing paint (for example, sand blasting) on steelwork may damage the galvanising coating of the bolt thread and will lead to corrosion.

b) All edges shall have a minimum radius of 2 mm. These requirements shall be included on the engineering drawings.

c) Welding shall be smooth or ground smooth, and all splatter shall be removed before painting.
d) Sharp re-entrant angles shall be avoided. All surfaces must be accessible to inspect, clean, sand back or other preparation, and repaint. Large surfaces meeting at angles of less than 45° are a future maintenance problem.

e) Rain shall wash all surfaces clean. Places where water and dust / mud can collect and accumulate must be eliminated by careful detailing.

f) Judicious use shall be made of non-corroding material, for example, stainless steel bolts, bearings and other details.

g) All hollow sections shall be joined using full penetration butt welds. Fillet welds are not acceptable for this application as they encourage crevice corrosion resulting in premature failure.

3.8.4 Durability for concrete

3.8.4.1 Components with 100-year design life

a) For road bridges and footbridges with 100-year design life, exposure classification shall be determined in accordance with AS 5100.5. The minimum exposure classification shall be B2 to AS 5100.5, except for reinforced concrete decks in remote areas where the appropriate concrete strength shall be selected after discussions with the region and potential suppliers.

b) In addition to 3.8.4.1 a), Table 3.8.4.1(a) for brackish saltwater and marine applications and Table 3.8.4.1(b) for Potential Acid Sulphate Soil (PASS) and/or Acid Sulphate Soil (ASS) environments shall also be met.

**Table 3.8.4.1(a) – Concrete exposure classifications for components in brackish, saltwater and marine applications**

<table>
<thead>
<tr>
<th>Location</th>
<th>Chloride content of water</th>
<th>Exposure classification</th>
</tr>
</thead>

</tr>
<tr>
<td>Tidal splash zones or zones subject to repeated wetting and drying in marine or saltwater</td>
<td>Above 8 000 ppm</td>
<td>C2</td>
</tr>
</tbody>
</table>

Note:
1. Tidal splash zone is the zone 1.0 m below Lowest Astronomical Tide (LAT) to 1.0 m above HAT.
2. Spray zone is the zone from 1.0 m above wave crest level where the structure is exposed permanently to salt spray or built over the sea.
3. Soffits of bridges and other structures which are in occasional contact with saltwater shall be exposure Classification C.

<tr>
<td>≥ 6000</td>
<td>C2</td>
</tr>
</tbody>
</table>

Note:

1. Full isolation of the concrete surface exposed to the environment by either protective coating, membrane or use of controlled backfill is also required for exposure classification C2 except for prestressed concrete driven piles and cast-in-place concrete piles which shall conform to items in Section 3.8.4.1 c) and e).

   c) Cover to reinforcement shall be as defined in AS 5100.5 except for the following:
   - for exposure classification C2 in salt water or marine applications as defined in Table 3.8.4(a) – 70 mm with rigid forms and intense vibration
   - for exposure classifications C, C1 and C2 for PASS / ASS as per exposure classification C in AS 5100.5, and
   - for driven prestressed concrete piles, minimum cover to reinforcement shall be 50 mm for exposure classification B2 to AS 5100. For all exposure class C applications including C, C1 and C2, the minimum cover shall be 70 mm with rigid formworks and intense vibration.

   d) Structural design for control of cracking shall be carried out, taking into consideration the exposure classification of AS 5100.5 Clause 4.3 and the minimum area of reinforcement in tensile zones according to AS 5100.5 Clause 8.6.

   e) Cast-in-place piles shall have permanent steel liners, and concrete shall be placed in the dry, where possible, and properly compacted. In marine or tidal applications, steel liners shall extend to a level 2.0 m above HAT.

   f) Bridge deck shall be waterproofed in accordance with MRTS84 Deck wearing surface.

   g) The requirement of proprietary high performance waterproofing membrane for special circumstances listed below shall be identified during the concept design stage to enable sufficient time for product evaluation. Such evaluation shall be undertaken outside a contractual situation.

   If a requirement of proprietary high performance waterproofing membrane has been identified at the concept design stage, the proposal to use such a system shall be informed in writing to the Director (Structures Review and Standards) for review and acceptance.

   The examples of special circumstances where proprietary high performance waterproofing membrane system shall be required:
   - transversely stressed deck unit bridges
   - rehabilitation of transversely stressed deck unit bridges
   - where bridge decks are suffering from high alkali reactivity
   - rehabilitation of decks where the deck reinforcing steel has been damaged or exposed, and
• bridge decks in salt spray susceptible areas.

h) Rail bridges shall conform to the rail authority requirements.

3.8.4.2 Components with 50-year design life

Exposures classifications and cover to reinforcement for components with a 50 year design life shall be as defined in AS 3600:2009 Concrete. The minimum exposure classification shall be A2.

3.8.4.3 Requirements for concrete strength, grade and mix design

Concrete shall be to MRTS70 Concrete. In addition to the requirements of MRTS70 Concrete, the following shall apply:

a) Minimum 28 days characteristic concrete strength and maximum aggregate size for relevant exposure classification shall be as follows:

- for exposure classification A2 and B1 to AS 3600, S32 to MRTS70 Concrete
- for exposure classification B2 to AS 3600 and AS 5100, S40 to MRTS70 Concrete
- for exposure classification C, C1, C2 and U (marine, tidal, saltwater or PASS / ASS conditions) to AS 3600, AS 5100 and this document, 50 MPa to MRTS70 Concrete.

The aggregate size shall be 20 mm.

b) With concrete for exposure classifications A2, B1 and B2 to AS 3600 and B2 to AS 5100, the following additional requirements for S32, S40 and S50 concrete mixes shall be met.

- minimum total cementitious content and maximum water cementitious ratio to be as per MRTS70 Concrete
- cementitious material to be a blend compliant with any of the following criteria with the combined total adding to 100%. Blend tolerances to be as per AS 1379:
  - 65% to 75% GP cement, 25% to 35% fly ash, or
  - 50% to 55% GP cement, 20% to 25% ground granulated blast furnace slag, and 25% to 30% fly ash, or
  - 65% to 71% GP cement, 4% to 8% amorphous silica, and 25% to 31% fly ash.

Maximum chloride ion content of hardened concrete is to be 0.8 kg/m³ for reinforced concrete and 0.6 kg/m³ for prestressed concrete.

c) With concrete for aggressive environments of exposure classifications C1, C2 to AS 3600 and C, C1, C2 to AS 5100, the following additional requirements for S50 concrete mixes shall be met.

- maximum chloride ion content of hardened concrete to be 0.4 kg/m³.
- minimum total cementitious content and maximum water cementitious ratio for C exposure classifications to be as per MRTS70 Concrete. For C1 and C2 exposure classifications, minimum total cementitious content to be 500 kg/m³ and maximum water cementitious ratio to be 0.4
cementitious material to be a blend compliant with either of the following criteria with the combined total adding to 100%. Blend tolerances to be as per AS 1379:

- 50% to 55% GP cement, 20% to 25% ground granulated blast furnace slag, and 25% to 30% fly ash, or
- 65% to 71% GP cement, 4% to 8% amorphous silica, and 25% to 31% fly ash.

3.9 Buried components (no inspection, maintenance practical)

Currently there are no additional requirements for durability of buried components; however, this will be a requirement in the future.

3.10 Aggressive environments

3.10.1 Sulphate reducing bacteria

a) Different types of Sulphate Reducing Bacteria (SRB) are located in many environments. The SRB most critical to steel bridge substructures are located in the rocks and soils of tropical Australia and Asia. The bacteria produce acid that attacks steel in the tidal range and within the soil, depending on the structural arrangement. The collapse of the Adelaide River Bridge in the Northern Territory has been attributed to sulphate reducing bacteria, which corroded steel piles at the mud line under water.

b) The Austroads Bridge Technical Review Panel is currently investigating SRB and is preparing technical advice on the subject.

c) Refer Section 4.1.6 for limitations to the use of steel piles.

d) Steel liners of cast-in-place piles are considered as temporary form work with no long-term structural capacity.

e) The use of temporary steel piles for structural capacity is permitted for a maximum design life of five years.

3.10.2 Stray currents from electric railway or other sources

Bridges in close vicinity to an electric railway shall be protected from stray current using a system accepted by the department and any related authority (for example, rail service provider).

3.10.3 Bridge components in marine environment

Cast-insitu concrete elements located in the tidal splash zone or zones subject to repeated wetting or drying salt water (chloride content above 8000 ppm), shall be designed for C2 exposure classification (refer to Table 3.8.4.1(a)) with a minimum 28 day characteristic strength of 50 MPa to MRTS70 Concrete and Section 3.8.4.3(c). Except where stainless steel reinforcement is used, a suitable outer layer of stainless steel reinforcement shall be provided, extending to at least 3 m above HAT, in addition to the inner layer of carbon steel reinforcement with excess cover. Stainless steel reinforcement shall conform to MRTS71A Stainless Steel Reinforcing and have sufficient cover to fully develop bond strength and ensure adequate placement and compaction of concrete. Cover to stainless steel reinforcement shall be 55 mm minimum. Gap between carbon steel and stainless steel shall be 50 mm minimum.

Carbon steel shall have provision for possible future cathodic protection and assessment of all concrete piles, pilecaps, headstocks and piers. This must include providing electrical continuity of all non-stressed and stressed reinforcement, fitments and anchor plates. Anchors for metal items
attached to concrete with a large exposed surface area must be electrically isolated from the surrounding reinforcement. The electrical continuity must be able to be demonstrated for all concrete piles, pilecaps, headstocks and piers. The electrical continuity shall be tested in accordance with AS 2832.5: Cathodic protection of metals – Part 5: Steel in concrete structures. These requirements shall be included on the appropriate project drawings.

This Section is not generally applicable to prestressed precast concrete piles or other precast items.

3.11 Cracks in concrete at the end of construction

a) In non-aggressive areas, any finished concrete with a crack more than 0.3 mm wide but less than 0.5 mm wide shall be:
   - inspected by the experienced Designer (who shall be an appropriate RPEQ) who shall certify that the crack is non-structural or structural
   - non-structural cracks shall be injected with epoxy to seal the crack by a means accepted by the department
   - cracks certified as structural shall be referred to the Director (Structures Review and Standards) who shall determine whether the crack shall be repaired or the member replaced, and
   - concrete elements with cracks greater than 0.5 mm shall be rejected.

b) In aggressive areas, any finished concrete with a crack more than 0.15 mm wide but less than 0.3 mm wide shall be:
   - inspected by the experienced Designer (who shall be an appropriate RPEQ) who shall certify that the crack is non-structural or structural
   - non-structural cracks shall be injected with epoxy to seal the crack by a means accepted by the department
   - cracks certified as structural shall be referred to the Director (Structures Review and Standards) who shall determine whether the crack shall be repaired or the member replaced, and
   - concrete elements with cracks greater than 0.3 mm shall be rejected.

3.12 Thermal cracking in large sections – modelling in design

Any concrete section with a thickness or minimum dimension greater than 1 m shall be thermal modelled by a recognised method to determine thermal gradient and maximum temperature due to heat of hydration. The maximum temperature of the concrete shall not exceed 75°C, and the thermal gradient from centre to surface shall not exceed 25°C. Thermocouples shall be placed in the structure to monitor the actual temperature. Where the temperature determined by thermal modelling is likely to exceed 75°C, the Designer shall submit a proposal for controlling the concrete temperature for Director (Structures Review and Standards) acceptance.
3.13 **Economy**

3.13.1 **Minimum whole-of-life costs**

All structures shall be designed for a minimum whole-of-life cost. The minimum whole-of-life cycle cost includes:

- initial construction cost
- inspection cost
- routine maintenance
- scheduled maintenance, and
- special maintenance.

The concept of building a cheap initial cost with high maintenance cost is not ‘value for money’ and will be rejected.

3.13.2 **Design details for economy**

The design shall be economically efficient. Economically efficient design shall be achieved by meeting one or more of the parameters such as lowest whole-of-life cost, lowest operating and maintenance cost, longest life span and so on.

3.13.3 **Constructability**

Method of construction shall be considered in the design and described in the design documentation. The construction process assumed in the design shall be reviewed at the pre-construction phase and reported. This review is to identify obstacles early in the project in an attempt to mitigate or prevent errors, delays, cost overruns and to ensure safety in design.

3.13.4 **Maintainability**

a) ‘Safety in design’ considerations mean that the Designer shall make provision for inspection and maintenance operations as part of the design process.

b) Maintainability shall consider the bridge’s future operating environment. As it is difficult to obtain closures of bridges carrying busy roads and railways, the design shall limit the range of materials to reduce the need for closures.

3.14 **Acceptable level of afflux**

a) In urban areas, the main restraint on hydraulic design is to minimise afflux when this would adversely affect adjacent upstream properties.

b) Permissible afflux effects shall be assessed in accordance with the department’s RDM and *Hydraulic Guidelines for Bridge Design Projects*.

c) Where afflux is not a restraint, care shall be taken to ensure velocity increase through the bridge opening is kept to levels consistent with the erosion potential of abutments, stream bed and banks downstream.

3.15 **Protection against scour**

The design scour event (that is, the event producing the highest velocity and greatest bed shear) may be a smaller event than the Annual Exceedance Probability (AEP) 0.05% flood event. Therefore, a range of floods up to and including that event shall be evaluated. Further guidance on the appropriate
selection of a scour design event and determination of depth of scour is included in the department’s *Bridge Scour Manual*.

### 3.15.1 Scour at abutments and piers

a) The scour potential at abutments and piers shall be minimised.

b) Piers and abutments shall be aligned with the expected flood flow directions. If at bed level, pile caps shall be detailed to provide minimum disturbance to the flow.

c) For new bridges, design of bridge piers shall not be relived on a pier scour protection. New bridges shall be designed by taking into account estimated maximum scour depth at piers to make sure structural integrity of the bridge under the action of scour. Pier scour protection is not applicable for new bridges.

d) Bridge abutments shall be designed by taking into consideration possible scour. Depth of scour shall be determined by scour analysis. Minimum scour depth for ultimate limit state design shall be 1% AEP scour depth or 2.0 m scour from the existing ground level at the abutment or bottom of the abutment headstock, whichever is lower. Where scour analysis shows that the abutment protection and associated embankment is removed with ultimate design flood event of 0.05% AEP, the bridge shall be designed for ultimate flood forces of 0.05% AEP event but without the accompanying traffic loads on the bridge.

e) Abutment scour protection shall be in accordance with Section 4.5.1.3.

f) The design life for an abutment / pier protection system in streams subject to scour is 50 years. The design must provide for replacement or repair of the scour protection at the end of its service life or after a flood event.

g) Scour protection at abutments and piers shall be designed for the maximum of average cross-sectional velocities for floods with an ARI between 1 year and 100 years, and shall consider situations such as:
   - overtopping bridge and bridge embankment
   - effects of local catchments and along road drainage, and
   - scour analysis based on actual particle size of bed material and bed shear stress (in sand, scour to more than 5 m are common).

h) If the overtopping event is greater than the ARI 100 (1% AEP) year event and less than the ARI 2000 year event, the Designer shall conduct a risk assessment to determine if the scour protection should be designed to withstand the overtopping event. The risk assessment should take into account the criticality of the link and availability of alternative routes, and potential cost of repairs versus the cost of scour protection.

The design life of scour protection (50 years) refers to the durability of materials used in construction of scour protection and shall not be confused with flood probability that the protection can be exposed. Design life of the protection is not possible to define with flood events because any flood event at the bridge has a certain AEP. The protection system should be sustain higher probable flood events to avoid frequent repairs; therefore, design criteria recommend to design the scour protection for higher flood velocity for floods with an ARI 1 year (100% AEP) to 100 years (1% AEP).
3.15.2 Handling drainage from adjacent road

Roadside drains must be designed and detailed to prevent erosion of the approach embankment and abutments. Road drainage must be moved away from the bridge where possible. Steep gradients into the stream must also be avoided where possible, or fully protected with lined channels and energy dissipaters when required.

3.15.3 Scour on drawings

Expected and acceptable levels of scour shall be shown on the design drawings.

3.16 Safety in design, construction and maintenance

Safety in design shall conform to:

1. *Work Health and Safety Act 2011*
2. Work Health and Safety Regulations
3. *Safe Design of Structures, Code of Practice*, July 2012, Safe Works Australia. This Code of Practice is yet to be endorsed by Queensland but is best practice in the absence of a local Code of Practice.

3.16.1 Safe access to site

a) The design shall address safety in the construction, inspection, maintenance and operation phases.

b) The design shall consider the future requirements for safe access for inspection and maintenance, including areas adjacent to the bridge where staff can safely park and load / unload equipment. This will require the designers of the adjacent roadway to include safe pull-off areas for vehicles.

3.16.2 Safe access for inspections (stairs, ladders, hatches, anchorage points)

- A bridge shall be designed with provision for maintenance access.
- Provisions for under bridge inspection requirements are defined in Section 1.3.2. Provisions for abutment bearing inspection are defined in Section 4.5.1.2.

3.17 Bridge security (when specified)

Bridge security considerations (where specified) may need to include the following:

- high security access to the inside of box girders and hollow piers (heavy duty galvanised steel (6 mm thick) doors and high security padlock systems)
- considerations of the redundancy of members and in spans
- installation of security cameras, and / or
- restricted access to site, typically around abutments.

3.18 Bridges over / in the proximity to railway

This section only applies to road, bus, light rail, cycle or pedestrian bridges near or over railway lines and is not applicable to railway bridges.
a) In addition to AS 5100, bridges over railway shall be designed in accordance with the current versions of following Queensland Rail Civil engineering technical requirements:

- Civil-SR-001 *Design of road overbridges*
- Civil-SR-002 *Work in and about Queensland Rail property*
- Civil-SR-003 *Requirements for work on or near high voltage overhead line equipment and low voltage services*
- Civil-SR-007 *Design and selection criteria for road / rail interface barriers*
- Civil-SR-012 *Collision protection of supporting elements adjacent to railways, and*
- Queensland Rail Standard Drawings.

b) Civil-SR-007 shall be amended as follows:

i. The requirements of the guideline are in addition to AS 5100 and AS/NZS 3845.

ii. Where a railway embankment has a vertical retaining wall, a traffic barrier shall be provided between the wall and the roadway where the height of the retaining wall is in excess of 2 m. The barrier shall be designed for impart loads unless the wall is designed for such loads. Where there is no barrier, the retaining wall shall be designed to withstand vehicle impact in accordance with AS 5100.

iii. Barriers on the edges of elevated retaining walls shall conform to the same criteria as bridges.

iv. Where road and rail bridges are parallel, the rail bridge superstructure could be subject to vehicle impact where it is less than 5 m from the road bridge barrier. In such cases, the bridge barrier shall be designed to prevent vehicle rollover. Consideration shall also be given to a rolling vehicle impacting the bridge substructure.

v. Table 7 (annotated as Table 5) in Civil-SR-007 shall be replaced by Table 3.18 which follows:

<table>
<thead>
<tr>
<th>Road status</th>
<th>Bridge barrier height (m) and barrier performance level to AS 5100</th>
</tr>
</thead>
<tbody>
<tr>
<td>1A</td>
<td>2.0 (Special)*</td>
</tr>
<tr>

<td>1.1 (Regular)</td>
</tr>
</tbody>
</table>

Note:

1. (Regular) denotes the barrier is 1100 mm high, measured from the edge of the adjacent road lane pavement level, with a barrier performance level “Regular”.

2. (Special)* is 1000 kN transverse barrier design load in accordance with Table 8 (annotated as Table 6) of CIVIL-SR-007, while Special is 750 kN.
3.19 Special conditions or requirements

Any special conditions, including aesthetics for the bridge design, are detailed in Chapter 7 (Item S1).
4 Bridge component design requirements

4.1 Foundation design

Geotechnical requirements in foundation design, including design methodology, geotechnical investigations, design documentations, pile testing and so on, shall be in accordance with Transport and Main Roads’ Geotechnical Design Standard – Minimum Requirements. In addition to that, requirements stated in this document shall also be met.

4.1.1 Driven piles – structural design

a) Structural design of driven piles shall be carried out in accordance with AS 5100.

b) PSC piles shall be designed with concrete strength at transfer shall be 35 MPa. Driven reinforced concrete piles are not permitted, except as part of very long PSC piles where the Reinforced Concrete (RC) section is buried at least 15 m below ground surface.

c) Driven prestressed concrete piles shall conform to Standard Drawing 2021 550 Octagonal PSC Piles – Earthquake classification BEDC-1, Exposure classification B2. Pile splices shall conform to departmental standards. Pile splices shall be located in a low moment zone at depth and are not permitted in Reinforced Soil Structure (RSS) blocks.

d) For abutment piles, displacement restraint and rotational restraint at the pile head must be minimised to reduce the internal pile forces (bending moments, shear forces) induced by lateral soil movement. Down drag (negative skin friction) effects due to settlement on piles must be allowed for in the design of such piles, together with methods to reduce such effects.

e) Lifting points for PSC piles shall be designed and RPEQ certified in accordance with MRTS73 Manufacture of prestressed concrete members and stressing units by the Designer.

The concrete strength at transfer has been assessed by Transport and Main Roads and casting yards as being suitable for a 24-hour turnaround cycle of a typical precasting yard using steam curing. Departmental evidence suggests that higher transfer strengths will affect precasting yard preferred production cycles, resulting in significant cost increases.

4.1.2 Cast-in-place piles – structural design

a) The minimum internal diameter of cast-in-place piles for traffic bridge foundations shall be 900 mm for those that do not require a safety shield for inspection and certification, and 1200 mm for all other applications.

b) Some cast-in-place piles require anchoring. Passive anchors (for example, reinforcing bars grouted into holes) are preferred. Active anchors (prestressed ground anchors) are not the recommended option. The preferred method of installing the reinforcing bar in the drilled hole of a passive anchor is for installation prior to placing the concrete.

c) The subsequent drilling of anchors from the surface through the concrete of the pile is NOT permitted because:

- the condition of the drilled hole (for example, clean or full of debris) cannot be determined
- any water ingress may adversely affect the quality of grout
• the integrity of the grout over the length of the pile cannot be guaranteed, and
• the reinforcing bar cannot be located centrally in the hole unless specialised fitments of proven performance are used.

\[\text{d) The steel liners shall be ignored in the durability assessment of the concrete piles.}\]

\[\text{e) Permanent steel liners of cast-in-place piles are considered as temporary formwork with no long-term structural capacity.}\]

4.1.3 Pile design outputs shown in drawings

The Designer shall calculate the following critical design loads for each pile for both serviceability and ultimate load cases, and these shall be clearly marked on the foundation drawings. For simplicity in construction, the maximum design effects in a pile group may be listed for all piles in the group:

• axial compression
• axial tension (if applicable)
• bending moments (in two directions)
• impact loads or lateral shear forces
• scour – design assumptions on maximum depth
• moment fixity in rock if required, and
• minimum penetration of the pile into the founding strata.

4.1.4 Pile design foundation levels

The Designer shall consider the bore logs and geotechnical report, and shall include on the drawings adequate information to guide the construction supervisors. This shall include:

• minimum depth / penetration of pile
• most probable founding level considering scour, axial and moment effects
• the founding layer or strata as described in the bore logs, and
• the likely geological requirements to achieve required geotechnical strength (service and ultimate).

Foundations are to be assessed on site by an experienced RPEQ geotechnical assessor.

4.1.5 Spread footings – structural design

Structural design of spread footings to be in accordance with AS 5100. Where spread footings are used as the abutment foundation, the requirements stated in Section 4.5.3 shall also be met.

4.1.6 Steel pile foundations

Steel piles are not permitted for bridge foundations; however, in dry western areas of Queensland, steel piles may be permitted in overflow bridges (not the main channel) where there is no permanent water and the ground is too hard for driven prestressed concrete piles. Prior written acceptance for the use of steel piles must be obtained from the Transport and Main Roads Director (Structures Review and Standards). The decision by the Director (Structures Review and Standards) will be based on technical merit, safety, constructability (hard driving conditions), maintenance, coatings and durability.
The use of temporary steel piles for structural capacity is permitted for a maximum design life of five years.

### 4.1.7 Raked piles

Raked piles may be used to provide lateral resistance of bridges. The structural effects on raked piles due to large settlement needs to be assessed at the concept design. Excessive loads on the raked piles may exclude the use of raked piles in those situations.

The Designer shall assess all load conditions in the temporary and permanent stages. The structural effects on raked piles due to any significant ground settlement has to be assessed at the concept design stage as excessive ground movement induced loads on raked piles may exclude their use in these situations. Also refer Section 4.1.1 (e).

Constructability of driving raked piles shall be considered by the Designer at the concept design stage. Consideration shall be given to:

- **a)** Rake angle, which should generally be limited to the range 1:8 to 1:10. Maximum rake angle shall be 1:8.
- **b)** Proximity of adjacent bridges or structures which may affect the working space to drive raked piles.
- **c)** Adjacent live traffic introducing higher safety risks.
- **d)** Spacing and offset of opposing rakers affecting access to drive adjacent piles after initial piles have been driven and to minimise trimming of piles to gain access to the next pile – offset and spacing also have to be balanced and matched pairs used to avoid introducing additional bending, torsion and shear effects in the pile cap.
- **e)** Sequence of installation, which may limit the use of raked piles; if other piles in the group have already been driven, it may not be possible to drive the last pile if it is raked.
- **f)** Layout of raked piles shall allow rig to be positioned for driving away from rig where possible; if driving PSC piles with an inward or lateral rake is unavoidable, Designer to ensure the pile design is constructible.
- **g)** Short raked piles are preferable to long piles which may require special measures for pitching and driving. Also longer piles have a higher risk of damage due to lateral forces on the raked pile during driving, and
- **h)** Pile splicing should be avoided where possible. If splicing is necessary, it is better to locate the splice in the lower section with a short starter pile. This will position the joint further down the pile during the harder driving phase when bending moments may be introduced due to the inclined driving.

It should be noted that the hammer efficiency will be reduced due to friction in the ram guides and it may be necessary to use a more powerful hammer than that required for driving vertical piles to the same depth. Raked piles shall be Pile Driving Analyser (PDA) tested and the results verified by testing of vertical piles in the group or structure.

### 4.2 Reinforced Soil Structure (RSS) walls

Refer Chapter 13 for RSS wall design requirements. Where RSS walls are used as the front face of the bridge abutment, the requirements stated in Section 4.5 shall also be met.
4.3 **Pile types not accepted by Transport and Main Roads**

The following foundation types are not accepted for use in bridge foundations:

- steel screw piles
- Continuous Flight Auger (CFA) piles
- precast reinforced concrete piles
- steel piles (except for Western Queensland, refer Section 4.1.6)
- precast concrete piles manufactured by spinning or rolling
- piles constructed with bentonite or polymer slurry, and
- bored piles without permanent steel or concrete liners.

Any proponent who believes the use of such piles is cost-effective and will achieve the strength and durability required may prepare a written submission for assessment by the department’s Deputy Chief Engineer (Structures). The Transport and Main Roads publication *Engineering Innovation* outlines the steps involved in the innovation process, which takes time and should ideally be done outside of a contractual situation, at the concept design stage.

4.4 **Pier designs**

4.4.1 **Headstocks**

a) The use of inverted ‘T’ headstocks is not a preferred option. The use of ‘thin’ bearing shelves designed as corbels is not permitted.

b) The use of precast headstocks or abutments is not permitted unless the design is as robust and durable as a cast-insitu design and is accepted by the Director (Structures Review and Standards).

4.4.2 **Durability**

Refer to Section 3.8 for durability of components of the bridge piers.

4.4.3 **Pier protection of overbridges from traffic impact**

Refer to Chapter 6 Part 2: *Design Loads*, Clause 10.2 of this document.

4.5 **Abutment designs**

4.5.1 **Spill-through abutments**

4.5.1.1 **Batter slope**

Spill-through abutments shall have a batter slope no steeper than 1:1.5.

4.5.1.2 **Access for inspections (walkways, stairs, ladders, hatches, anchorage points)**

a) A 750 mm minimum width shelf shall be incorporated at or near the top of the batter slope to allow access to inspect and maintain bearings.

b) On major bridges, the design shall include the provision of access gantries for future maintenance. On smaller bridges, the installation of support points to support future maintenance activities shall be considered. Other access requirements include:

- platforms at abutments to allow safe inspection of bearings
• drains in the platform shall be covered with grating to prevent trip hazard
• stairways to access locations and on batter slopes to access abutments
• ladders, fixed where this is appropriate, or attachments to stabilise temporary ladders
• hatchways to provide access and prevent unauthorised entry - hatchways shall be a minimum width of 750 mm
• anchorage points for inspection scaffold or safety harness
• where required, appropriately designed handrails shall be provided, and
• access to inspection platform shall not be provided from the road under the bridge to restrict unauthorised person access to the steps and inspection platform.

c) Eyelets shall be cast into the sides of abutment headstocks for attachment of safety lines for inspections and maintenance. Eyelets shall be hot dipped galvanised; however, marine grade stainless steel eyelets shall be used in marine or corrosive environments. Eyelets shall be made of 16 mm diameter steel minimum.

4.5.1.3 Abutment scour protection

The department’s Bridge Scour Manual provides guidance on how to assess and accommodate scour into bridge design. This manual shall be consulted for detailed guidance regarding abutment slope protection.

Table 4.5.1.3 shows the referenced Standard Drawings for abutment scour protection types and its application selection criteria.

</table>

(a) Stream velocity (V) = Average stream velocity at bridge cross-section.
(b) Subgrade soil condition shall be determined in consultation with project geotechnical engineer.
(c) Currently there is no Transport and Main Roads Standard Drawing for this protection type. Project specific design to be developed to suit.
(d) Preferable to use for repair of damaged bridges, not for new bridges and widening.
(e) Flood free overpasses.
4.5.1.3.1 Abutment protection for widened bridges

The abutment protection of a widened bridge shall be similar in style and materials to the existing bridge, provided the original protection is in reasonable condition. If the existing protection is in poor condition or has failed, a complete new protection shall be provided.

4.5.1.3.2 Abutment protection – all bridges

a) Abutment slope protection shall be provided for all bridges, except where the abutment is founded on a non-friable rock cutting.

b) Abutment slope protection for road overbridges shall be provided at least over the area directly beneath the superstructure, and over sufficient of the embankment sides to prevent erosion and undermining. Protection shall be provided along the embankment to at least past the back of the relieving slab unless otherwise shown in Standard Drawings. A suitable toe shall also be provided.

c) Abutment height shall be considered in determining the length of a bridge. High abutments result in large retaining structures and embankments with inherent stability issues, both in terms of the surcharge load to underlying materials causing risk of excessive settlement, and the consequent long-term structural issues, including rotations and horizontal deflections. Instances have occurred where vertical and horizontal displacements at high abutments in soft soils have resulted in structural distress to the abutment and consequent jamming of expansion joints.

d) The material for the abutment slope protection shall:
   • blend in and harmonise with the existing surrounds and proposed landscaping and urban design
   • require minimal maintenance over the service life of the bridge
   • be structurally stable and resistant to weathering, and
   • have a uniform plane surface and suitable neat appearance.

e) The material selection shall be considered in context with the landscape concept and other surrounding elements.

f) Abutment slope protection shall be designed in accordance with the minimum standards of MRTS03 Drainage, Retaining Structures and Protective Treatments.

4.5.1.4 Abutments designed for soil settlement and movement

a) Where the bridge approaches overlie soft compressible layers of soil, the permissible total in service settlement (within the first 40 years in service) shall be in accordance with Table 1 Settlement Criteria specified in Transport and Main Roads’ Geotechnical Design Standard - Minimum Requirements.

b) Raked piles shall not be used where significant settlement is expected unless a full analysis of long-term ground movements confirm that the abutment pile forces are within safe limits. Refer to Section 4.1.7 for general raked pile requirements.
4.5.2 Reinforced soil structure walled abutments

a) Where RSS walls are used as the front face of the abutment, the Designer shall incorporate in the design a primary support system for the abutment headstock (such as PSC or cast-in-place piles) with a design life of at least 100 years.

b) Where the abutment headstocks are designed to be tied back into the RSS block, the Designer shall provide supporting information demonstrating that the tie-back straps for the headstock have 100 years' design life with the proposed backfill material as required by the RSS supplier's specification.

c) A walkway shall be provided between the abutment headstock and the RSS wall for bridge inspections and maintenance. The RSS wall shall extend a minimum of 1100 mm above the top of the walkway surface to provide protection for users of the walkway. Alternatively, a balustrade with a minimum height of 1100 mm shall be provided. The walkway shall have a clear width of 1200 mm between the front of the headstock and the back face of the wall panel or the balustrade. The vertical head clearance shall be 2000 mm minimum between the soffit of the girders or deck units and the top of the walkway.

Both ends of the walkway shall be secured with robust locked gates to prevent unauthorised entry. A path shall be provided at both ends of the walkway connecting the bridge approach to the walkway. Balustrades shall be provided along the path.

The Designer shall consider access limitations and the method of providing materials and equipment for bridge maintenance and bridge jacking.

4.5.3 Abutment spread footings

Abutments that are supported on spread footings shall be founded on competent rock acceptable to the Transport and Main Roads Director (Geotechnical), and not on rock or soil that is strengthened by rock / soil anchors or by other means. Abutments shall be founded on piled foundations in the absence of competent rock for spread footings.

4.6 Bearings

Refer Section 3.7.1 for the design life of bearings.

The minimum edge distance between the end of a girder or deck unit and the bearing or support plate shall be 75 mm.

4.6.1 General

Articulation of a widened bridge shall be consistent with the existing bridge articulation.

4.6.1.1 Widened bridges

The bearings on widened bridges shall be similar to the existing type in the bridge. Steel components of pot bearings shall be hot dip galvanised to AS/NZS 4680 or stainless steel. Bridge substructures shall be designed for the load effects of jacking of superstructure to replace bearings.
4.6.1.2 New bridges

The following changes apply to the bearing arrangement for bridges:

a) All bridges consisting of deck units with insitu deck shall have a bearing under each end of the deck units.

b) For transversely stressed deck units with span length of 21 m or greater, each end of the deck unit shall be supported on a suitable bearing.

c) For transversely stressed deck units with span length of less than 21 m, the deck units may be supported on either mortar pads (preferred) or bearings.

d) All other superstructure types shall be supported on bearings.

4.6.2 Provision for jacking and bearing replacement

a) Bridge superstructures and substructures must be designed to allow for future jacking and bearing replacement. A jacking procedure including number of jacking points shall be included in the design report and drawings at the concept design.

b) Diaphragms shall be provided at each end of every span for all girder bridges. End diaphragms shall be designed to carry the self-weight of the span and emergency vehicles through jacking devices positioned on headstocks. The gaps between bottom of the end diaphragms and top of headstock shall be a minimum of 200 mm (nominal). The location points and the associated maximum jacking loads must be addressed and detailed in the design documentation. The Designer shall submit a comprehensive maintenance procedure detailing the equipment and the methods to replace the bearings. The jack capacity shall be twice the design working load. Fasteners on bars in shear are not permitted.

c) Bearing pedestals shall be constructed using concrete or accepted proprietary mortars developed specifically for installation of bearings. Bearing pedestals shall be a minimum depth of 150 mm. Bearing pedestals shall be reinforced.

d) Girder bearings shall be on continuous or on discrete pedestals 150 mm deep (nominal). The width of headstocks shall be sufficient to accommodate jacking devices for direct jacking of girders or deck units.

e) All girder bearing pedestals shall be reinforced cast in situ concrete with a minimum depth of 150 mm and a plan area that provides an edge clearance that ensures bearing forces intersect the vertical reinforcing bars. These shall be cast separately to the bearing shelf. All fasteners shall be anchored within the pedestal rebar grid and any restraint angles must have at least the minimum edge clearance described above. Typically the concrete strength shall be a minimum of 50 MPa, but load effects must be checked. Normally, a 10 mm aggregate would be used to allow a grid of small diameter bars at relatively close centres.

f) The provision of pedestals allows much greater control of line and level and a means of compensating for errors in headstock construction line, level and planarity.
g) Where the superstructure span is fixed at one end (for example, continuous deck structure or deck structure integral with pier), the member stress limits contained in these design criteria and AS 5100 must not be exceeded at any time during jacking of the free end for bearing replacement or maintenance.

4.6.3 Restraint of elastomeric bearings

Elastomeric bearings shall be in accordance with AS 5100. Elastomeric bearings including strip bearings, shall be restrained from creeping in any direction. This can be achieved either by:

- Installing steel bearing restraint plates attached to the underside of girders, or
- Placing the bearings or strips in 10 mm deep recesses in the headstock or reinforced concrete pedestals. The recesses shall be initially constructed to a greater depth and then filled with epoxy mortar to achieve 10 mm deep recess for the bearings. Recesses into mortar seatings are not permitted. Concrete cover to headstock reinforcements shall be measured from the bottom of the recess.

4.6.4 Unacceptable types of bearings

Disc bearings (using proprietary plastic type discs) and spherical bearings are not permitted.

4.6.5 Design for hog during construction

Design hog values at various stages (transfer, erection, deck casting and so on of construction) and the elastic modulus used for the hog calculation shall be shown in the project drawings.

4.6.5.1 PSC deck units on elastomeric bearings

A layer of epoxy putty with a thickness not greater than 5 mm shall be placed on top of the elastomeric bearings to accommodate rotation due to beam hog. This shall be applied insitu during deck unit erection just prior to lowering the deck unit onto temporary packers adjacent to the bearing. Notes to this effect must be included on the project drawings.

4.6.5.2 PSC girders, including T-girder bridges

a) For T-girder bridges, tapered plates shall be used between the bearing and girder to accommodate the effect of hog in the PSC girders. The minimum thickness of plates shall be 16 mm. The plates shall be fully dimensioned and detailed on the drawings.

b) To ensure uniform bearing between the tapered plate and the girder, a plate with minimum thickness of 16 mm shall be cast into the underside of the girder. The plate thickness may need to be increased to provide anchorage of studs to anchor the plate.

c) The use of a layer of epoxy putty or mortar on top of elastomeric bearings, in lieu of a tapered steel plate, is not permitted.

4.7 Main superstructure elements

4.7.1 Positive connection required

a) Superstructures of all bridges shall be positively connected to the substructure by means such as reinforced concrete shear block with vertical dowels, restraint angles or holding-down bolts or shear blocks with pins. Floating superstructures on bearings relying on friction are not permitted.

b) Positive hold down connection shall be provided where required to resist uplift.
c) Bridge decks integral with the abutment are not permitted for any temporary or permanent works, unless the bridge is designed and detailed as a portal frame.

d) Drilling or coring into PSC girders and PSC deck units is not permitted. Provisions for restraints must be detailed on the drawings and cast-in when the units are cast.

e) Provision for effective lateral restraints to resist lateral movement during jacking for bearing replacements shall be made for all bridges.

4.7.2 External post-tensioned concrete superstructure

Permanent external prestressing is not permitted.

4.7.3 Prestressed concrete deck units

4.7.3.1 Prestressed concrete deck unit ligatures

a) The ligatures in PSC deck units are placed above the bottom layer of prestressed strands and in contact with the underside of the second row of strands. The exception is the sets of ligatures at the ‘ends’ of the deck units, where the ligatures enclose all the prestressed strands, including the bottom layer of strands. The ‘end length’ comprises the first debonding length plus development length of the strand (60 x strand dia.) or 1000 mm whichever is greater.

b) The reason for requiring ligatures to be placed in this location is that the strands provide support, and assist with maintaining the correct concrete cover at the bottom of the deck unit. This reduces durability issues and provides significant time saving for manufacturers.

c) Designers shall be aware that the effective depth used in torsion and shear calculations would need to be reduced accordingly.

d) Ligatures that are not in accordance with a), must have some other positive means of support detailed so that they do not settle under intense vibration during casting.

e) Strands located in corner of ligatures shall not be debonded.

4.7.3.2 Maximum skew angle

a) Deck units shall not be cast with skews exceeding 45°. This requirement relates to practicality of manufacture.

Note: When the skew of the superstructure exceeds 45°, this can be achieved by installing the deck units on the actual skew, but ends of the precast girders shall be detailed at 45° (acute angle of the girder ends).
Chapter 4: Bridge component design requirements

b) The ligatures shall be fanned at the ends and transition to be perpendicular to the deck unit longitudinal axis.

c) Where transversely stressed deck unit bridges are designed on skew of 30° or greater, longitudinal shear must be addressed in the design including consideration for shear keys.

4.7.3.3 Voids in Prestressed concrete deck units

Maximum void length in PSC deck units shall be 2.0 m. A minimum of 60 mm cover is required between the void and strand and / or horizontal reinforcing steel to ensure the flow of concrete around the void.

4.7.3.4 Transfer strength of prestressed concrete deck units

PSC deck units shall be designed with concrete strength at transfer greater than or equal to 35 MPa, and less than or equal to 40 MPa.

The upper limit of concrete strength at transfer has been assessed by Transport and Main Roads and casting yards as being suitable for a 24-hour turnaround cycle of a typical precasting yard using steam curing. Departmental evidence suggests that higher transfer strengths will affect precasting yard preferred production cycles resulting in significant cost increases. Where the casting yard is part of the Alliance, Designers shall obtain approval from the department for transfer strengths in excess of 40 MPa due to the cost implications.

4.7.3.5 Lifting of Prestressed concrete deck units

Lifting points for PSC deck units shall be designed and RPEQ-certified in accordance with MRTS73 Manufacture of Prestressed Concrete Members and Stressing Units by the Designer.

4.7.3.6 Waterproof membrane

A waterproof membrane in accordance with MRTS84 Deck Wearing Surface shall be provided for the entire bridge deck for all deck unit bridges.

4.7.3.7 In-fill sheets

In case the deck units are spaced apart, the permanent form work for deck slab shall be in accordance with Section 4.7.5.5.6

4.7.4 Prestressed concrete I-girders

4.7.4.1 Transfer strength of prestressed concrete I-girders

PSC I-girders shall be designed with concrete strength at transfer greater than or equal to 35 MPa, and less than or equal to 40 MPa.

The upper limit of concrete strength at transfer has been assessed by Transport and Main Roads and casting yards as being suitable for a 24-hour turnaround cycle of a typical precasting yard using steam curing. Departmental evidence suggests that higher transfer strengths will affect precasting yard preferred production cycles, resulting in significant cost increases. Where the casting yard is part of the Alliance, Designers shall obtain approval from the department for transfer strengths in excess of 40 MPa due to the cost implications.
4.7.4.2 Diaphragms

I-girder superstructures shall be designed with a diaphragm between girders at each pier and abutment to ensure uniform distribution of loads during jacking to replace bearings. In addition, intermediate diaphragms shall be provided between girders to resist impact loads from excessive height vehicles or high marine vessels. For road overpasses, intermediate diaphragms shall be aligned with the centre of the marked traffic lanes on the carriageway below.

4.7.4.3 Lifting of Prestressed concrete I-girders

Lifting points for PSC I-girders shall be designed and RPEQ-certified in accordance with MRTS73 Manufacture of Prestressed Concrete Members and Stressing Units by the Designer.

4.7.5 Prestressed concrete Super T-girders

4.7.5.1 T-girder dimensions

- Super T-girders shall have diaphragms and the maximum void length between diaphragms shall be 5.0 m.
- T-girder dimensions and void arrangements shall be in accordance with Figure 4.7.5.1 and Table 4.7.5.1 respectively.

#### 4.7.5.2 End diaphragms

a) T-girder superstructures shall be designed with a diaphragm at each pier and abutment to ensure uniform distribution of loads during jacking to replace bearings.

b) T-girder diaphragms or cross girders shall be poured separately from the reinforced concrete deck because the diaphragms provide stability during pouring of the concrete deck. The diaphragms shall be poured and the concrete cured before the deck is poured. This shall be detailed on the drawings.

#### 4.7.5.3 Maximum skew angle

a) Concrete trough and ‘Super Tee’ girders shall not be cast with skews exceeding 45°. This requirement relates to practicality of casting yards.

Note: When the skew of the superstructure exceeds 45°, this can be achieved by installing the Super T-girders on the actual skew, but ends of the precast girders shall be detailed at 45° (acute angle of the girder ends).

b) The ligatures shall be fanned at the ends and transition to be perpendicular to the girder longitudinal axis. Refer Transport and Main Roads’ Drafting and Design Presentation Standards Manual, Volume 3 - Structural Drafting Standards, Chapter 14 for typical reinforcement arrangement at the skew ends of the girders.

#### 4.7.5.4 Half-joints not permitted

Stepped or half-joints shall not be used in bridge girders.
4.7.5.5 Sacrificial formwork for Super T-girders

The sacrificial formwork for the in situ reinforced concrete deck over Super T-girders and between the flanges of Super T-girders shall comply with the following requirements.

4.7.5.5.1 Design loads and load combinations

a) The design loads to be applied to the formwork are:
   - self weight, and
   - construction loads.

b) The limit state design factored load combinations for strength, stability and stiffness (deflection) shall be in accordance with AS 3610 Formwork for Concrete Table 4.5.1

4.7.5.5.2 Construction loads

The construction loads on the formwork shall be considered in two stages. Stage 1 is prior to the placement of the concrete deck and Stage 2 is during the placement of the concrete deck.

a) Stage 1 loads:
   - Concentrated load that shall be in accordance with AS 3610. This load shall be multiplied by 1.25, which is the recommended impact factor.
   - This load can be due to construction materials, such as bundles of reinforcing steel and construction foot traffic.

b) Stage 2 loads:
   - wet concrete, and
   - concentrated load which shall be in accordance with AS 3610.

Wet concrete and concentrated load shall be multiplied by 1.25 (dynamic impact factor). These loads take into account the placement of the concrete. They also take into account the loads generated by construction foot traffic and the equipment used in the placement of the concrete.

4.7.5.5.3 Edge support of formwork

The minimum edge support dimension shall be 25 mm continuous along four sides of the formwork. The strong direction of the formwork shall span across the T girders.

4.7.5.5.4 Acceptable deflection

The deflection shall be determined in conjunction with the load combinations specified in AS 3610 Table 4.5.1. The maximum allowable deflection for all stages of construction shall be span/360 for all products.

4.7.5.5.5 Strength limit state design

The maximum ultimate limit state stresses for load combinations in AS 3610, Table 4.5.1 for all stages of construction shall be less than the specified design flexural strength of the material.
4.7.5.5.6 In-fill sheets

a) Fibre Cement (FC) in-fill sheets

FC sheet is an accepted material for in-fills to Super T-girders. The design criteria for the FC sheet shall satisfy the following:

- the deflection shall be in accordance with the acceptable deflection criteria, and
- the ultimate design stresses shall not exceed the design flexural strength of the panels.

b) Material not permitted as in-fill sheets

The following materials are not permitted as in-fill sheets in Super T-girders:

- Plywood and wood-based panel products because moisture ingress degrades the material, which may then block drainage of the cells in the girder.
- Cold-formed steel sheet sections are not permitted due to deformation of profile during loading.

c) Alternative products

i. Any product except those listed under Section 4.7.5.5.6 b) as in-fill sheets may be considered an alternative product.

ii. The product shall satisfy the following:

- resist the design loads
- be durable for 100 years
- satisfy the deflection criteria outlined previously, and
- the cross-sectional shape shall not change when the formwork is loaded. Testing may be required to verify the section does not change shape.

iii. The product shall be selected by the Designer, and detailed clearly on the deck drawings.

4.7.5.6 Transfer strength of prestressed concrete Super T-girders

PSC Super T-girders shall be designed with concrete strength at transfer greater than or equal to 35 MPa, and less than or equal to 40 MPa.

The upper limit of concrete strength at transfer has been assessed by Transport and Main Roads and casting yards as being suitable for a 24-hour turnaround cycle of a typical precasting yard using steam curing. Departmental evidence suggests that higher transfer strengths will affect precasting yard preferred production cycles, resulting in significant cost increases. Where the casting yard is part of the Alliance, Designers shall obtain approval from the department for transfer strengths in excess of 40 MPa due to the cost implications.

4.7.5.7 Debonding of strands

Strands located in corner of ligatures shall not be debonded.
4.7.5.8 Lifting of Prestressed concrete Super T-girders

Lifting points for PSC Super T-girders shall be designed and RPEQ-certified in accordance with MRTS73 *Manufacture of Prestressed Concrete Members and Stressing Units* by the Designer.

4.7.6 Prestressed concrete box girders

4.7.6.1 Segmental superstructure construction

a) The preferred option involving precast segmental sections is that all joints between precast sections must have an insitu concrete connection and must be a minimum of 400 mm wide with lapped reinforcement.

b) Match-cast segmental superstructure construction may be used only in exceptional circumstances, subject to departmental acceptance by the Deputy Chief Engineer (Structures). The criteria listed in Section 4.11.6.2 shall be used as the basis of a submission to use match cast precast concrete boxes.

4.7.6.2 Design criteria

4.7.6.2.1 General

a) All permanent prestressing shall be internal.

b) Grouting of internal prestressing ducts shall be in accordance with MRTS89 *Post-Tensioned Concrete*.

c) The dimensional tolerance of wide units is critical, as large differences in thickness can result in cracking. As large dimension units can cause instability, the maximum dimension of a precast box shall be 14 m.

4.7.6.2.2 Durability

a) A multi-redundant system shall be used to ensure that there is no water ingress resulting from the use of match cast systems.

b) All concrete shall be cured in accordance with MRTS70 *Concrete*. No reduction in curing standard will be permitted.

c) All faces between match cast units shall be coated with wet-to-dry epoxy.

d) All prestressing ducts shall be in accordance with Clause 7.1.6 of MRTS89 *Post-Tensioned Concrete* (steel ducts are not permitted).

e) A proprietary seal shall be used on all ducts at each match cast joint.

f) The entire width of the top surface of the deck shall have a 20 mm x 20 mm recess joint between the match cast boxes and sealed with a waterproof joint after stressing.

g) The entire top surface shall be sealed with a high-performance waterproof membrane with a grit to ensure grip of the DWS. Bituminous waterproofing to MRTS84 *Deck Wearing Surface* is not permitted.
4.7.6.2.3 Design

a) The standards which shall be used in the design of PSC box girders are listed in Table 4.7.6.2.3(a).

b) There will be a residual compression of 1 MPa for ALL serviceability load cases.

c) Tapered shear keys shall be used on each match cast joint.

4.7.6.3 Additional segmental bridge design standards not covered in AS 5100.

a) AS 5100 and the previous criteria shall be the main reference for design. However, where this Standard does not specifically address match cast box girders, AASHTO LRFD may be used.

b) The standards which shall be used for segmental bridge design and construction of prestressed concrete segmental bridges are listed in Table 4.7.6.3.

Table 4.7.6.3 – Segmental bridge design standards

<table>
<thead>
<tr>

<td>Analysis of Segmental Bridges</td>
</tr>
<tr>
<td>AASHTO LRFD</td>
<td>Section 5.14.2</td>
<td>Segmental Construction</td>
</tr>
</tbody>
</table>

i. AASHTO LRFD Section 4.6.2.9:

- specific requirements for the analysis of time dependent effects
- specific requirements for transverse analysis of box sections
- specific requirements for erection analysis.
ii. AASHTO LRFD Section 5.14.2
- specific requirements for construction analysis
- definition of minimum construction loads (out of balance segments, erection equipment, and so on)
- specific requirements for limiting stresses during construction
- construction load combinations
- considerations for provisional post-tensioning ducts and future deflection adjustment
- specific requirements for minimum section dimensions
- specific requirements for seismic design
- specific requirements for segmental joints (precast and insitu joints)
- specific requirements for balanced cantilever construction
- specific requirements for force effects due to construction tolerances
- segmental bridge design detailing requirements
- specific requirements for segmental bridge substructures.

4.7.6.4 Precast segmental bridge deck analysis
The method of analysis for precast segmental bridges is specifically covered in AASHTO LRFD Section 4.6.2.9. The following issues are to be considered in addition to those required for standard precast girder decks:
- shear lag (effective flange widths)
- construction stage analysis
- prestress stage analysis
- analysis for time-dependent effects, in particular the concrete segment creep and shrinkage properties which vary with time
- residual creep effects
- torsional and distortional warping for box sections, and
- construction loads.

4.7.6.5 Lifting of Prestressed concrete box girders
Lifting points for PSC box girders, where applicable, shall be designed and RPEQ-certified in accordance with either MRTS72 Manufacture of Precast Concrete Elements or MRTS73 Manufacture of Prestressed Concrete Members and Stressing Units as applicable by the Designer.

4.7.7 Steel I-beams
Steel I-beams are less durable than prestressed concrete unless regularly painted and maintained. They are acceptable when widening an existing steel beam bridge, and shall be galvanised where possible.

For new bridges, painted girders are generally not acceptable because of the ongoing costs of regular inspection, cleaning and painting, including the cost of traffic control and disruption to traffic.
4.7.8 Steel box girders

4.7.8.1 Cost benefit analysis

Steel box girder construction may be used only in exceptional circumstances, subject to departmental acceptance by the Deputy Chief Engineer (Structures) prior to commencing the design. The choice of design option is based on the option’s whole-of-life cost as well as on the constraints that may prevent using concrete girders. The Designer shall submit the whole-of-life cost for this option and an alternative non-steel option (for example, concrete box girder option).

4.7.8.2 Design criteria

The criteria for steel box girder design shall include but not limited to the following:

a) Design life – the design life shall be interpreted such that there is a 95% probability that, during the design life of the structure or element, it:
   - will not require major maintenance or replacement
   - will be functional
   - will require minimal maintenance, and
   - will blend and harmonise with the existing surrounds and planned landscaping.

b) Durability.

c) Robustness.

d) Access for inspections.

e) Access for maintenance to re-apply protective coatings if not hot dipped galvanised.

f) Constructability during fabrication and erection.

g) Compliance with MRTS78 Fabrication of Structural Steelwork.

4.7.8.3 Design standards

Steel bridges are to be designed in accordance with AS 5100, except that, for the design of steel box girders, the standard detailed in Table 4.7.8.3 must apply during the erection stage.

Table 4.7.8.3 – Steel bridge design standards

<table>

</tr>
</tbody>
</table>
4.7.8.4 Maintenance access

a) Any steel box girder over a road, rail or shopping corridor shall be provided with a maintenance gantry attached to the structure. The design of the maintenance gantry shall be such that when the maintenance gantry is in use, it will not intrude into the clearance envelope of all surrounding corridors.

b) The boxes shall be large enough to allow easy internal inspection, maintenance and painting. A minimum size of 1.6 m internal depth x 1.2 m wide is required.

c) There must be sufficient clearance beneath the bridge to allow inspection and painting without interruption to the traffic underneath.

d) Rails for an access gantry must be included in the design, and drawings of a fully detailed access gantry must be supplied.

e) All steel box girders must have access holes suitable for inspection and maintenance access. Access holes must be located in the bottom flange in areas of low stress, and must be fitted with hinged doors and provided with locks.

f) Access holes must be provided in all diaphragms.

g) Access holes must be large enough to permit maintenance personnel access.

h) Access provisions must comply with the Work Health and Safety Act 2011 and the Work Health and Safety Regulation 2011 which include, but are not limited to, the provisions for the design of confined spaces.

4.7.8.5 Ventilation and drainage

a) Provision must be made for ventilation and drainage of the interior of all box sections.

b) All outside openings in steel box sections must be screened to exclude unauthorised persons, birds and vermin.

4.7.8.6 Durability

a) All steelwork, including internal faces, shall be protected by hot dip galvanizing to AS/NZS 4680. Refer additional requirements in Section 3.8.1 for steel with low silicon and low phosphorous contents.

b) All steel surfaces are to be protected from corrosion.

c) Internal areas too small to paint (including maintenance repainting) must be sealed and filled with either an inert gas or a water-absorbing product such as Corroless™. Sealed sections shall be pressure tested prior to inserting the gas or water absorption products. Bolts must be provided with inspection tabs to monitor internal conditions for all sealed sections.

d) The interior of all steel box sections must be painted with a light colour.

e) The coating system shall be shop applied.

f) Coating systems must be capable of being repainted by brush. A trial test panel must be undertaken before repainting steel box girder bridges.

g) Coating systems must be applied in accordance with the manufacturer’s specifications and Transport and Main Roads Technical Specifications.
h) The coatings shall have a 25 year design life. The paint coating system shall include the recoating procedure for maintenance.

4.7.9 Steel composite bridge deck

a) The method of analysis for steel composite bridges is covered in AS 5100.6 Section 7B.4, the analysis method being selected according to Table 4.7.9.

Table 4.7.9 – Steel composite bridge analysis method

<table>
<thead>
<tr>
<th>Limit state</th>
<th>Method of analysis</th>
</tr>
</thead>
<tbody>
<tr>
<td>Serviceability limit state</td>
<td>Linear elastic</td>
</tr>
<tr>
<td>Ultimate limit state</td>
<td>Two-dimensional ‘Grillage’ analysis for global effects</td>
</tr>
<tr>
<td></td>
<td>Three-dimensional finite element analysis</td>
</tr>
</tbody>
</table>

b) The following issues are to be considered in the analysis of steel composite girder decks:

- shear lag (effective flange widths)
- ratio of elastic modulus between concrete and steel
- concrete cracking (in particular over pier supports for continuous bridges)
- torsional and distortional warping for box sections
- plate slenderness limits (compact vs non-compact sections)
- element buckling
- member buckling (for example, lateral torsional buckling), and
- construction stage analysis.

4.7.10 Proprietary bridge deck systems

Proprietary bridge deck systems shall be a Transport and Main Roads approved product. The departments approved proprietary bridge deck systems and suppliers are listed in Proprietary Design Index for Bridges and Other Structures.

4.7.10.1 Wide flange I girders

Sample Wide Flange I girder type shape is shown in the Figure 4.7.10.1.

Figure 4.7.10.1 – Wide flange I girder shape
The department is procuring the complete structural system for the specific project, not just the girder. The selection of the deck system using this girder type shall consider the following:

- implications on vertical and horizontal alignment
- transportability and handling from precast yard to the site
- feasibility and stability / safety of erecting the girders
- girder design shall ensure that the appropriate type of bridge bearings (such as pot bearings for large loads) are used. Also selected bearing type shall offer low maintenance and ease of bearing replacement options.
- differential heights between adjacent girders for superelevation
- use of end diaphragms for torsional stability
- effects of skew and so on.

For shorter spans, the flange width would be wider than for longer spans, due to the use of fewer girders per span for short spans.

In comparison with other standard girder types, if the technical capability and functionality is the same, the most cost effective utilisation / application of girder type will dictate the preferred design.

Bridge deck system using Wide Flange I girders shall be designed in accordance with this document and the registered supplier’s technical manual.

### 4.8 Decks and deck wearing surface

#### 4.8.1 Crossfall, gradient and drainage

a) The drainage system must be designed so that a minimum amount of water flows across deck joints. All drainage structures must be readily accessible for cleaning and maintenance purposes.

b) Bridge drainage over streams shall satisfy the requirements of the Environmental Management Plan (EMP). In general, collection and treatment of drainage water is not required unless specified in the EMP. Where drainage pipes are required, they must be able to be cleaned effectively, and placed between beams or behind an edge skirt to maintain clean lines on the bridge profile.

c) To prevent structural overloading from flooding due to leaks and breakages in the pipe, stormwater pipes shall not penetrate into the voided cell of Super T-girders and deck units unless a 100 mm diameter drain hole is detailed in the bottom flange of the cell containing the pipe. In addition, drain pipes inside any cell or box girder shall be galvanised (hot dipped) steel pipe.

#### 4.8.1.1 New bridges

a) The crossfall on all new bridges shall be compatible with the geometric road design. The minimum crossfall on new bridges shall be 2.5%.

b) If the bridge is submersible, then zero longitudinal gradient is acceptable. This will minimise undesirable turbulence effects when the bridge is progressively inundated.
4.8.1.2 **Widened bridges**

a) The minimum crossfall shall be similar to the existing bridge deck. The preferred minimum crossfall is 2.5%.

b) The existing DWS on all bridges subject to widening, including bridge approaches where required, shall be milled off to a sufficient depth to allow for a new asphaltic concrete (AC) DWS. Milling shall be in accordance with MRTS84A *Removal of Bridge Deck Wearing Surface*.

c) For existing bridges having a one-way crossfall of less than 2%, the DWS may be increased in thickness to result in a crossfall of 2%, provided the load rating is not too adversely affected.

d) Where the proposed crossfall has a significant adverse effect on load rating due to increasing DWS thickness, the proposal shall be submitted to the Director (Structures Review and Standards) for acceptance.

4.8.2 **Waterproof membrane**

a) A bituminous waterproof membrane in accordance with MRTS84 *Deck Wearing Surface* shall be provided for the entire bridge deck of all bridges.

b) For bridges with a footway raised above the concrete deck using fill, the bituminous waterproof membrane on the deck shall extend under the raised footway areas to protect the bridge deck from corrosion. Stabilised sand shall be used where fill is required under raised footway areas on bridge decks to eliminate moisture being retained on the top of the deck.

4.8.3 **Deck wearing surface**

a) The Deck Wearing Surface (DWS), where applicable, on all road bridges must be asphaltic concrete and must have a minimum design life as specified in MRTS30 *Asphalt Pavements*.

b) The Dense Graded (DG) AC and Open Graded (OG) Asphalt in DWS must comply with MRTS30 *Asphalt pavements*.

c) Construction of DWS shall be in accordance with MRTS84 *Deck Wearing Surface*.

d) On PSC deck unit bridges without a cast in situ deck slab, the DWS shall consist of a dense graded asphalt corrector course followed by a waterproof membrane and a surfacing layer. The corrector course shall have a minimum thickness of 25 mm in any trafficked lane. The corrector course shall not be less than 10 mm at the kerb. Where the surfacing layer consists of open graded asphalt, the maintenance requirements shall note that the waterproof membrane could be removed during resurfacing and has to be reinstated.

e) On bridges with a cast in situ deck, the DWS shall consist of a waterproof membrane and a surfacing layer. Where the surfacing layer consists of open graded asphalt, an additional layer of dense graded asphalt shall be placed under the waterproof membrane to protect the deck during removal of the open graded asphalt and the maintenance requirements shall note that the waterproof membrane could be removed during resurfacing and has to be reinstated.

f) The minimum thickness of DWS (excluding bituminous waterproof membrane and corrector course as noted above) on bridges shall comply with MRTS30 *Asphalt Pavements*.
g) The minimum DWS thickness to be allowed in design shall be in accordance with MRTS30 Asphalt pavements Table 8.6.1 and as noted below:

i) For two-way crossfall carriageways on PSC deck unit bridges without a cast insitu deck slab, the minimum DWS thickness shall be 85 mm on trafficked lanes (70 mm at kerb). This minimum DWS is consisting of 25 mm minimum AC7H corrector course (10 mm at kerb), 10 mm waterproof membrane and 50 mm AC14H surfacing layer. The Designer shall increase the DWS thickness, if necessary, to ensure minimum 25 mm thick corrector course under the traffic lanes allowing for crossfall and minimum thickness at kerb.

ii) For one way crossfall carriageways on PSC deck unit bridges without a cast insitu deck slab, the minimum DWS thickness shall be 85 mm. This minimum DWS consists of 25 mm minimum AC7H corrector course, 10 mm waterproof membrane and 50 mm AC14H surfacing layer.

iii) For bridges with a cast insitu deck slab, the minimum DWS thickness shall be 60 mm. This minimum DWS consists of 10 mm waterproof membrane and 50 mm AC14H surfacing layer.
iv) For bridges with a cast in situ deck slab where the final layer is OG asphalt, the minimum DWS thickness shall be 95 mm. This minimum DWS consist of 50 mm AC14H base layer, 10 mm waterproof membrane and 35 mm OG14 surfacing layer.

### 4.9 Bridge traffic barriers

#### 4.9.1 General

Bridge traffic barriers shall be provided in accordance with this Section. Refer Transport and Main Roads Road Planning and Design Manual (RPDM) for barrier requirements for other structures (non-bridge).

#### 4.9.1.1 Structural design

All new bridge traffic barriers shall conform to AS 5100 and further requirements are detailed in Chapter 6 Additional requirements to AS 5100 Bridge design. The minimum design load for barriers on new bridges shall be ‘regular’ level to AS 5100. For details for bridge widening and replacement of existing barriers, refer to Chapter 7 Matters for resolution to AS 5100.

#### 4.9.1.2 Functionality and appearance

- **a)** The primary function of a traffic barrier is to contain or redirect vehicles.
- **b)** Features of a barrier system that are designed to limit injury to vulnerable road users shall be documented. These features may include some or all of the following:
  - a smooth unbroken surface without openings or sharp edges
  - lack of points that might snag
  - protection against impact with posts
  - locating attachments, such as reflectors, where they are less likely to be impacted, and
  - on terminals, the vertical slope on a road traffic barrier shall be no steeper than 1 (V) to 10 (H). Frangible attachments, defined as having a maximum section dimension of 90 mm with 5 mm wall thickness for square, rectangular or circular sections in accordance with AS/NZS 1163, shall have a maximum slope of 1 (V) to 2(H).
- **c)** These features shall be part of the basic design or obtained by fitting additional components.

#### 4.9.1.3 Post and rail traffic barriers

Steel (posts and rails) bridge traffic barriers shall be used on bridges over streams, creeks and rivers with a flood immunity of less than ARI 2000 years to reduce afflux, if this is a design constraint.
4.9.1.4 Concrete barriers

a) Concrete traffic barriers shall be used on overpass bridges. Details of cover plates at expansion joints are provided in Section 4.10.

b) The following methods for constructing concrete traffic barriers on bridges are not permitted:
   - slip forming of concrete traffic barriers and median barriers, and
   - extruding concrete barrier.

c) Concrete traffic barriers and median barriers on bridges shall be cast integral with the bridge deck using reinforcing steel. The traffic barrier loads shall be transferred to the deck using reinforced concrete design methodology.

4.9.1.5 Precast concrete barriers

Precast concrete traffic barriers shall conform as follows:

a) Reinforcing bars connecting the barrier to the deck are to be uniformly spaced – approximately 150 mm apart.

b) Precast barriers fixed to the bridge deck with only concrete stitch pours or joints are not acceptable. A precast outer face with a cast insitu concrete inner face (each part 100 mm minimum thick) to full height of the barrier is acceptable. The cross-section shall enable easy vibration of the concrete to the full depth of the barrier.

c) Grouting reinforcing bars in small holes does not guarantee quality, hence, these designs are not acceptable.

d) Recessed holes are not acceptable.

e) Where a bridge is to be widened on one side and the existing barriers are substandard by current design requirements, the need to modify or replace the old barrier (on the non-widened side) shall be clarified in Chapter 7 Matters for resolution to AS 5100 in the design brief.

f) In addition to the requirements in this document, precast barriers shall be designed to MRTS72 Manufacture of Precast Concrete Elements where applicable including requirements for lifting.

4.9.1.6 Transition between road and bridge barriers

The transition from road barriers to bridge barriers must ensure:

a) there is no snagging hazard to stop the errant vehicle moving between the two types of barrier

b) the entire length of the road barrier, transition and bridge barrier must be smooth and continuous to support an errant vehicle’s passage along the carriageway

c) the stiffness of the barrier must ensure pocketing does not occur; bridge transition barriers are detailed in Transport and Main Roads’ Standard Drawings, and

d) refer to Chapter 6 Additional Requirements to AS 5100 Bridge Design in this document for further details.
The approach rail shall not direct an errant vehicle into a hazard on the bridge (for example, kerb). Similarly the exit shall not direct a vehicle onto a hazard. The layout must also address crossover crashes / incidents. The approach barrier also stops an errant vehicle from travelling down embankments, into creeks or onto a road beneath the bridge. The design method of road barriers is based on risk assessment. Details of the method, including determining the length of approach barriers, are listed in Part 6 of Volume 3 of the RPDM 2nd Edition.

The balustrade will narrow the footpath width. Additionally, a balustrade may pose a hazard to cyclists.

4.9.1.7 Retrofit of barriers

With regard to design for retrofit existing barriers and new barriers on existing bridges and approaches, the following shall apply:

a) Balustrades are on the outside of footpaths.

b) Traffic barriers are on either side of a bridge to restrain errant vehicles.

c) Balustrades shall not be installed on the road side of a footpath / bikeway on new Works. Traffic barrier plus safety rail shall be used in these applications.

d) Historically, balustrades may have been installed between road and footpath to stop pedestrians and cyclists falling off the footpath on to the road where there is a large vertical drop to the road or where the footpath is narrow. Vehicle impact of balustrades poses a hazard to road users and pedestrians.

e) On existing bridges with balustrades next to the road, the balustrade may be allowed to remain in place if the speed limit is 70 km/h or less and commercial vehicles are less than 5% traffic volume. All other applications shall be removed and replaced by conforming barriers.

f) Traffic rails / barriers MUST NEVER be connected to the end of a balustrade.

For the assessment process refer to Figure 4.9.1.7.
**Figure 4.9.1.7 – Flow chart for assessing bridge barriers and transition to roadside safety barriers**

- If bridge edge barrier is not warranted, approach roadside safety barriers are not required. Check delineation requirements.
- Check - is bridge edge barrier warranted? (Refer to "Design Criteria for bridges and other structures" and AS 5100 Cl.1.2)
- New bridge edge barrier is required. (Refer to "Design Criteria for bridges and other structures")
- Was/is there an existing bridge edge barrier?
- Has the bridge edge barrier, and/or bridge approach roadside safety barrier been damaged?
- No further action required
- Bridge approach roadside safety barrier damage only
- Design appropriate bridge approach roadside safety barriers. (refer to "Road Planning and Design Manual, Chapter 8- Safety Barriers and Roadside Furniture").
- Bridge edge barrier damage only
- Review the capacity of the bridge edge barrier and provide appropriate transition/connection between the bridge approach roadside safety barrier to the bridge edge barrier. (Specialist TMR advice may be required.)
- Both bridge edge barrier and bridge approach roadside safety barrier damage.
- Design bridge edge barrier (refer to "Design criteria for bridges and other structures") with appropriate bridge approach roadside safety barriers and appropriate transitions/connections between the roadside safety barrier to the bridge edge barrier.
- Design both bridge edge barrier and bridge approach roadside safety barrier (refer to "Design criteria for bridges and other structures" and Road Planning and Design Manual chapter 8) including appropriate transitions/connections between the bridge edge barrier and the roadside safety barrier.

### 4.9.1.8 Design for temporary barriers – worker protection during construction

When workers and / or work areas are behind the barrier, both the Designer and the Contractor have safety in design obligations under legislation. Additionally, due to safety in design considerations, the Designer has a duty to ensure that there is no foreseeable risk to the workers during construction. Temporary barriers shall be designed to comply to the provisions in accordance with AS 5100.1 Appendix B, except Figures B5 to B8 are replaced by Table 4.9.1.8 and Figure 4.9.1.8.
While design of temporary barriers may be the responsibility of the Contractor, the permanent Works Designer has a safety in design responsibility to ensure the Works can be carried out safely. This shall be addressed in Safety In Design (SID) workshops during the design phase. For example, assess the safety aspects during staged construction or widening of bridges while under traffic and incorporate control measures for identified risk. The permanent Works Designer has to allow for all temporary work load effects in the permanent Works design.

Figure 4.9.1.8 – Deemed-to-comply temporary barriers to AS 5100 to protect workers – 45 t semi-trailer and 68 t B-double
4.9.2 Wire rope barriers

Wire rope barriers shall not be used on bridges.

4.9.3 Noise barriers, safety screens and electrical protection barriers on bridges

a) Where noise barriers, safety screens and electrification barriers must be continuous across the bridge, it is a requirement that the noise barrier panels and posts and electrification barriers shall be located on the outside of the bridge behind the top horizontal face of the concrete traffic barrier to avoid being impacted by traffic.

b) The requirement for and design criteria for safety screens must be in accordance with the following departmental documents:
   - technical guidelines for the treatment of overhead structures – objects thrown or dropped, and
   - policy – reduction of risk from objects thrown from overpass structures on to roads.

c) Provision for anti-jump screens:
   - risk analysis shall be undertaken to assess whether anti-jump screens are required
   - the methodology shall be similar in principle as that used for anti-throw screening on overpass structures
   - factors to consider include the following:
     - height of bridge / structure (>25 m), geographical location, social-economic situation
     - whether the structure is iconic / landmark that effects undesirable attention and so on
   - options to consider include:
     - installation of anti-jump screens in the current project at the time of construction, or
     - make provisions in the structure for easy / practical installation of anti-jump screens in future, should the need arise, and
   - in any case, the structure shall be designed to include loads resulting from the anti-jump screens.

4.9.4 Barriers between footpath / cycle path and bridge carriageway

a) A traffic barrier is recommended between the shared paths (foot / cycle paths) and the carriageway when one or both of the following conditions are present:
   - speed limit of the road is 70 km/hr or greater, and / or
   - footpath / cycle path is used by a high percentage of young children (for example, the path is located near a school), regardless of the vehicle speed.

b) Where barrier between footpath / cycle shared path and carriageway is required as per the above criteria, rigid traffic barrier with a pedestrian / cycleway balustrade constructed to the appropriate height above the traffic barrier as shown in Figures 4.9.4(a) and 4.9.4(b) as appropriate shall be provided. The height of the barrier shall be in accordance with AS 5100.1 and designed for loads in accordance with AS 5100.2. This barrier shall have following characteristics:
• The front face of the pedestrian rail shall be set back a minimum of 100 mm behind the road face of the traffic barrier. In addition to this, the front face of the cycleway barrier (for pedestrian and cycle shared paths) shall be set forward a minimum of 150 mm in front of the inside edge of the raised kerb.

• Where a traffic barrier has an additional high rail for pedestrian / cycle safety, this rail, including its connections and joints, shall be designed so that it shall not come loose in the event of a vehicle impact and spear into the vehicle.

• Where footpath is used by a high percentage of young children (for example, the path is located near a school), a non-climbable ‘protection panel’ shall be attached to the bridge barrier on footpath side. This protection panel shall start at 150 mm clear from the top of the concrete kerb and extend up to the pedestrian safety rail as shown in Figures 4.9.4(a) and 4.9.4(b). The protection panels shall be galvanised for durability and made of:
  - vertical rods of 16 mm diameter minimum at 150 mm spacing, or
  - steel perforated sheet of 1.6 mm thickness.

c) Where a barrier between footpath / cycle path and carriageway is not required as per above criteria (generally in suburban areas), a 300 mm high non-mountable kerb with a vertical face as shown in Figure 4.9.4(c) shall be provided. A balustrade shall be provided at the edge of the bridge and no bridge traffic barrier is required. The kerb shall be flushed with the shared path pavement surface level to avoid pedestrian trip hazard.

Figure 4.9.4(a) – Barrier between carriageway and shared path

![Figure 4.9.4(a) – Barrier between carriageway and shared path](image-url)
d) Rigid traffic barriers should have transition in the vertical plane at a maximum slope of 1 in 10. Frangible attachments in traffic barriers shall have a maximum slope of 1 (V) to 2 (H).

e) The pedestrian barrier shall have transition at 1 in 10 in the vertical plane if it is non-frangible. Frangible barriers can transition in a vertical plane.

f) Frangible barriers are defined as 90 mm maximum dimension with 5 mm wall thickness for square, rectangular or circular section based on AS/NZS 1163.
Chapter 4: Bridge component design requirements

4.9.5 Criteria to protect existing bridge supports

Refer to Chapter 6 for requirements to protect new bridge supports.

a) Existing bridge supports that are within the road reserve shall be protected from vehicle impact using an appropriate barrier system as shown below. In addition to the protection barrier, the bridge support shall be checked for the following impact loads:
   - for vehicle speed equal to 100 km/hr or higher, the bridge support shall be checked for impact load of 2000 kN
   - for vehicle speed less than 100 km/hr, the impact force can be reduced by a factor \((V^2 / 100^2)\), where \(V\) is the vehicle speed, but minimum impact force shall not be less than 1000 kN.

b) The possible angle of impact shall be determined by a risk analysis but minimum impact angle shall be 15° from the direction of the road centre-line passing under the bridge. The load shall be applied 1.2 m above ground level. The effective contact length of the load is the smaller of the contact length on the support (for example, width of pier) or 2.4 metres. This load, in conjunction with the ultimate design dead loads on the structure, shall be considered at ultimate limit states, with a load factor of 1.0.

c) Where bridge support capacity is not sufficient, strengthening may be required.

d) If the existing bridge piers and abutments consist of column type structures, they may require retrofitting with reinforced concrete ‘infilling’ between individual columns to provide a blade structure for robustness and structural adequacy for impact resistance.

4.9.5.1 Protection of bridge supports within the 10 m clear zone

Bridge supports that are within the clear zone (not less than 10 m) shall be protected using a TL5 rigid road barrier for speeds greater than 80 km/h and TL4 road barrier for speeds less than or equal to 80 km/h as a minimum barrier requirement complying with the requirements of Section 11.2 of AS 5100.2 with appropriate approach treatment. The barriers shall be designed so as to not transmit the barrier design load to the bridge supports. However the design barrier performance level shall be determined using the barrier selection method in AS/NZS 3845 and the department's RPDM. The design performance level of the barrier may be greater than TL5, depending on the results of the barrier selection method.

a) A rigid reinforced concrete barrier shall be used unless there are drainage considerations that requires an open steel rail and post barrier. Appropriate foundations shall be used to limit deflections of the barrier to prevent transmission of the barrier design load to the bridge supports.

b) A rigid barrier is refined as having zero or extremely limited deflection, movement or yielding deformation when impacted by an errant vehicle. Examples of rigid barrier are extruded or cast insitu concrete barrier restrained at the base. A precast concrete barrier is not a rigid barrier.

c) Guardrail, W-beam, Thrie-beam and wire rope barriers are not permitted.

d) The protection barrier shall extend at least 6 m beyond the end of the protected structure in both directions, or longer if required by the risk assessment, and a transition provided to
standard road barrier for continuation to the total length. For road safety requirements, the barrier alignment and total length of barrier shall be in accordance with the department’s RPDM.

4.9.5.2 Protection of bridge supports outside the 10 m clear zone

a) Acceptable barrier types are extruded concrete barriers, structural steel rail and post or G9 (modified) Thrie-beam (AS/NZS 3845) barriers for the protection of bridge supports that are located more than the clear zone of 10 m.

b) The selection of barrier type is subject to the results of a risk analysis taking into account the modification factor for horizontal curve, slopes and so on in Chapter 8 of the RPDM. The minimum acceptable barrier is the G9 (modified) Thrie-beam.

c) Wire rope barriers shall not be used to protect bridge supports from vehicle impact.

d) The protection barrier shall extend at least 6 m beyond the end of the protected structure in both directions, or longer if required by the risk assessment, and a transition provided to standard road barrier for continuation to the total length. For road safety requirements, the barrier alignment and total length of barrier shall be in accordance with the department’s RPDM.

4.10 Expansion joints

4.10.1 General

Expansion joints design shall conform to AS 5100 and the additional requirements:

a) Bolted-in extruded aluminium expansion shall only be used when the road surface is asphalt. Cast-in extruded aluminium expansion joints shall be used only when the road surface is concrete.

b) Expansion joint replacement: Expansion joints shall be designed to be replaced during the life of the bridge. Where the joint is secured by bolts, the bolts and sockets shall be corrosion resistant stainless steel, of two different grades to prevent thread locking on tightening.

c) Joint seals: Joint seals on all bridges (including bridge widenings) must be continuous across the width of the bridge and any edge upturns.

d) Abutment stiffness: If expansion joints are provided at an abutment, the design must include raked piles or stiffer cast-in-place piles to prevent earth pressure moving the abutment forward and closing the joint.

e) Bearing replacement: Where bearings are used at abutments, a joint must be provided to enable jacking for bearing replacement.

f) Waterproof: All types of joints shall be waterproof, with adequate seals and drainage to prevent road runoff from staining piers and abutments, or causing corrosion damage to bearings or restraints.

g) Constructability: Joints must not inhibit the proper placement and compaction of deck concrete.

h) Maintenance: Joints must have adequate access for inspection and maintenance.
i) Surface flatness: The surface flatness of joints must not deviate by more than 3 mm when measured with a 3 m straightedge. This includes the adjacent surface seals and cover plates.

4.10.1.1 Safety of pedestrians and cyclists

The surface of joints must not present a hazard to any road user. Joints on roadways shall be detailed to be safe for narrow bicycle wheels. Joints on footpaths/cycleways shall have no gaps that can trap a bicycle wheel, and must not present a slippery surface when wet.

4.10.1.2 Noise

Joints must be selected and detailed to minimise noise produced by traffic crossing the joint.

4.10.1.3 Modular joints

Modular joints shall be designed in accordance with Transport and Main Roads’ Technical Specification MRTS90 Modular Bridge Expansion Joints and AS 5100. Modular joint design shall provide adequate space in the void beneath the joint to permit easy access for inspection, maintenance, and replacement of critical wearing components of the joint. The overall bridge design shall include safe access to the space beneath the joint.

4.10.1.4 Finger type expansion joints

Finger type joints such as fingerplate or saw tooth expansion joints shall be designed in accordance with Transport and Main Roads Technical Specification MRTS82A Finger Type Bridge Deck Expansion Joints and AS 5100.

Gap width of fingerplate joints shall be as follows:

- For fingerplate joints, the gap width specified in AS 5100.4 Section 17.3.5 shall be amended, as the maximum opening between fingers between adjacent fingers on the same side of the joint shall be 60 mm and minimum overlap of the fingers on the opposite side of the joint shall be 15 mm. This is as shown in Figure 4.10.1.4(a).

**Figure 4.10.1.4(a) – Gap width of fingerplate expansion joints**

- For saw tooth joints, the maximum perpendicular opening between adjacent saw teeth on the opposite side of the joint shall be 60 mm at the ultimate movement limit and the minimum overlap of the saw teeth on the opposite side of the joint shall be 25 mm. This is as shown in Figure 4.10.1.4(b).
Figure 4.10.1.4(b) – Gap width of saw tooth expansion joints

Maximum 60 mm gap in the perpendicular direction

Saw Tooth joint

4.10.2 Non-conforming joints

a) The following joints inclusive do not conform to departmental requirements, and shall not be used in any bridge design:
   - Multiplex™ and WABOFLEX™ joints are not acceptable due to the high noise level produced on previous departmental projects.
   - flush seals that are flush with the deck wearing surface shall not be used for aluminium strip expansion joints for skew greater than 20°
   - bonded steel plate / rubber type joints, or
   - simple open joints, as they are not waterproof.

b) If there is evidence, supported by design change, in-service performance and independent assessment and testing, a Designer may submit such information before the 85% complete design report to request acceptance to use any of the joints listed in (a) above.

4.10.3 Joints to be detailed on drawings

Expansion joints shall be fully detailed on the project drawings.

4.10.4 Cover plates at joints

a) Stainless steel cover plates with a minimum thickness of 6 mm shall be provided on concrete traffic barriers at expansion joints, where the maximum opening in the barrier is greater than 150 mm but less than 900 mm under the worst serviceability limit state condition (widest opening). Where the maximum opening in the barrier is less than 150 mm, steel cover plates with a minimum thickness of 3 mm shall be provided.

b) The opening is measured parallel to the longitudinal axis of the bridge.

c) Steel cover plates must cover the inside face and top of the barrier.

d) The faces of the barrier shall be recessed so the cover plate is flush with the barrier surface except that recesses in the faces of the barriers are not required for 3 mm thick plates.
4.10.5 Design for access of safe maintenance

Access for safe maintenance of the expansion joint system is a part of the design development process. This requirement needs to be addressed at the concept design stage and reviewed through the detail design. The principle method adopted by the design to address safe maintenance shall be to reduce or eliminate maintenance requirements.

4.10.6 Open joints

Open joints are prohibited.

4.11 Relieving slabs

a) Relieving slabs shall be provided at both ends of road bridges in accordance with Standard Drawing 1505 - Bridge approaches - Relieving slab 3 metre span (3 m span) to prevent settlement of the road surface adjacent to the structure.

b) Relieving slabs shall be fixed to the bridge abutment, with the typical detail in Standard Drawing 1505 which allows limited rotation under settlement.

c) Design change of grade over the length of the relieving slab due to differential settlement during design life of the road pavement shall be limited to 0.5%.

d) Where there are very high embankments (typically > 6.0 m high) and / or residual future settlement, relieving slabs shall be provided in accordance with Standard Drawing 1506 (6 m span).

4.12 Stay cables

a) For cable stayed bridges, provisions must be made for the replacement of the stay cables in the long term. To facilitate this requirement, the bridge must be designed to allow any one cable to be removed without exceeding any serviceability limit states.

b) A detailed procedure for the replacement of stay cable shall be included on the drawings, noting any live load restrictions required, and all jacking loads and precautions.

4.13 Services, lighting, miscellaneous

4.13.1 Provision of utility services on bridges

a) The design must satisfy the requirements of all relevant authorities to accommodate and provide for existing and proposed future services acceptable to the department within and / or on the bridges.

b) The service ducts in the footpath may be placed in the cavity, spanned with precast reinforced concrete panels or, alternatively, the cavity may be filled with weak concrete.

4.13.2 Fixings for services

a) Fixings cast into bridge concrete shall have a high level of durability. The minimum level of durability is hot dip galvanised fittings except that, in marine environments, the fittings shall be marine grade (Grade 316) stainless steel.

b) The criteria need to address durability, load and performance during an extreme event. Parameters to be addressed include:

• drilling into prestressed or post-tensioned members is not permitted
• the attachment point for services shall be adequately anchored into the bridge
• for bridges over streams, the services are positioned above the soffit of the superstructure to ensure there is no additional blockage of the waterway area and to maintain clean lines of the bridge
• where the services are positioned exposed to the flooding, they shall be designed to ensure they can sustain impact from the flood debris and water flow in accordance with Section 3.4.1(b)
• services shall be supported on the abutment or extend behind the abutment
• services that are attached to the bridge deck (including between the deck units or girders) shall not be encased in concrete
• gas pipes shall be located in well-ventilated open areas of the bridge, and
• where light posts are to be fixed to the bridge, the junction box shall be located not greater than 500 mm away from the centre of the post base plate fixed to the bridge.

4.13.3 Chemical anchors in tension
   a) Chemical anchors in tension are not permitted (for example, suspending a pipe underneath a bridge deck).
   b) Permanent fixtures must be cast into concrete for service support. Chemical anchors are acceptable for fixings loaded in shear.

4.14 Footbridges and bikeways

4.14.1 Special conditions for short span, narrow footbridges not over road or rail corridor
   a) The individual spans of foot and / or bicycle path bridges that do not pass over a road corridor (including clear zone, or rail corridor), and have:
      • spans less than 10 m
      • width less than 3.4 m, and
      may be designed for bored piles or cast-in-place piles with a minimum diameter of 600 mm in accordance with MRTS63A Piles for Ancillary Structures.

4.14.2 Maximum gradient
The maximum gradient of pedestrian bridges shall conform to Transport and Main Roads Technical Note 38 Longitudinal Grades for Footpaths, Walkways and Bikeways.

4.15 Paint systems

4.15.1 Initial application to be compatible with future recoating
   a) Any paint system specified must include details of how the coating shall be repainted in the future. The recoat system must be practical and compatible with normal operating systems, for example:
      • abrasive blasting onsite is difficult and undesirable
      • the closure of some lanes for repainting is not possible on highly trafficked roads; similar conditions shall apply to other transport corridors, and
• all coatings shall be able to be applied by airless spray, brush, roller, and air. The first coating system must be applied in the shop. Recoats would be field applications.

b) Any painted steelwork (for example, gantry or bridge) over a road, rail or shopping corridor shall be provided with a maintenance gantry attached to the structure. The design of the maintenance gantry shall be such that when the maintenance gantry is in use, it does not intrude into the clearance envelope of all surrounding corridors.

c) All bolts, rivets and edges shall be stripe coated. All paint shall be applied in accordance with MRTS88 *Protective coating for new work*.

4.15.2 Medium exposure (C3 to AS 2312 and AS 4312)

In a medium (C3 to AS 2312 and AS 4312) exposure application and a 25 year coating life, acceptable paint systems for fabricated steelwork over a transport corridor as well as for repainting steel bridges are listed in *Product Information for Bridges and Other Structures*.

4.15.3 Very high marine exposure (C5M to AS 2312 and AS 4312)

In a very high marine exposure (C5M to AS 2312 and AS 4312) application where a 25-year life is required, acceptable paint systems for fabricated steelwork are listed in *Product Index for Bridges and Other Structures*.

4.16 Structural steel

Structural steel material shall meet the following requirements:

• All cold formed structural steel hollow sections shall be to AS/NZS 1163 Grade XXXL0 where XXX is the grade of the steel.

• Steel members fabricated from rolled plates with seam welds need to be designed taking into account the tolerance of rolling in the design. The tolerances are outlined in MRTS63 *Cast-in-place piles*. Rolled plates shall be manufactured in accordance with MRTS63 *Cast-In-Place Piles* using Grade XXXL15 material to AS/NZS 3678 where XXX is the grade of the steel. All of these welds shall be 100% ultrasonically tested.

• All hot rolled steel plates shall be to AS/NZS 3678.

• All structural steel hot rolled sections shall be to AS/NZS 3679.1.

• Structural steel welded sections shall be to AS/NZS 3679.2.

• Minimum steel thickness for structural steel members shall be 2.5 mm except for external steel members exposed to weather where the minimum steel thickness shall be 3 mm.

• Structural steel water pipe manufactured to AS 1579 is not permitted unless it is tested along the longitudinal axis to AS/NZS 1163 and is Grade XXX L0 where XXX is the grade of the steel.

• Spirally wound fabricated circular hollow sections are not permitted.
5 Additional requirements – bridges

5.1 Date plates and survey marks
A date plate (Standard Drawing 2005) and a survey mark shall be detailed in the design documents and affixed to each bridge.

5.2 Inspection during construction and on completion of bridges
The following requirements for inspection during construction and on completion shall be included in the design documents.

5.2.1 Inspection on completion of construction
a) The new bridge construction work shall have a Level 2 inspection carried out by a qualified inspector on completion of the construction in accordance with the department’s Structures Inspection Manual and the results entered into the department’s Bridge Information System (BIS).

b) The Level 2 inspection shall be undertaken prior to placing of DWS while the top of the deck units or reinforced concrete decks are accessible for inspection.

5.2.2 Multi-span bridges
On multi-span bridges, the Level 2 inspection shall be undertaken after construction of a few spans to identify issues early and avoid repetition of errors on the remaining spans.
# 6 Additional requirements to AS 5100 *Bridge design*

In this chapter, the clause number refers to AS 5100.

## Part 1: Scope and general principles

| Clause 9.5 Edge clearances for bridges with walkways |
| In addition to the requirements of Clause 9.5 for bridges without walkways, the minimum edge distance is 600 mm for bridges unless a greater width is required in Tables 9.4(A) and 9.4(B). |

| Clause 10.5.2 |
| Replace this clause with the following: |
| For certain bridge sites, conditions may be such that traffic barriers may constitute a higher risk than not providing any barrier. Similarly, traffic barriers need not be provided on low-level bridges subject to frequent flooding. Traffic barriers may be omitted where ALL the following conditions apply: |
| • the bridge is less than 1.5 m above the ground or low flow water levels |
| • traffic volumes are less than 150 vehicles per day |
| • radius of curvature of the bridge is such that the road approaches have a sight distance greater than the minimum stopping distance for the design speed of the road |
| • the width between kerbs is not less than 8.4 m for a two-lane bridge or 5.2 m for a single lane bridge |
| • the edge of the bridge is at least 1.0 m from the edge of traffic lanes |
| • the location is without anticipated pedestrian / cycle traffic |
| • any water beneath the bridge is normally less than 1.2 m deep |
| • the provision of barriers would prevent the passage of debris or the barriers would be frequently damaged by heavy debris or both, and |
| • where a risk assessment has been undertaken and it has been agreed with the Director (Structures Review and Standards) that barriers are not to be provided. |

| Clause 10.6.3 |
| A smooth face and tensile continuity shall be maintained throughout. Exposed bridge traffic barrier ends, posts and sharp changes in the geometry of the barrier components, kerbs, and the like, shall be avoided or transitioned out with a maximum taper of: |
| • 1 in 10 in the horizontal plane |
| • 1 (V) to 10 (H) in the vertical plane |
| for the barrier components, and a maximum taper of 1 in 20 for kerb discontinuities. Frangible attachments are defined as having a maximum section dimension 90 mm 5 mm wall thickness for square, rectangular or circular section based on AS/NZS 1163, and shall have a maximum taper of: |
| • 1 in 10 in the horizontal plane |
| • 1 (V) to 2 (H) in the vertical plane. |

| Clause 11.4 Ship collision with bridge piers |
| Paragraph 2 of this clause is deleted. |

| Clause 12.1(d) Height of balustrades |
| This clause states that the balustrade shall be 1.3 m above the kerb. |
| Austroads Guide to Road Design Part 6A Pedestrian and cyclist paths Clause 7.7 states that the balustrade shall be 1.4 m (minimum 1.2 m) above the riding surface. |
| In order to conform to both documents, a minimum height of 1.4 m must be used. A kerb is required under the balustrade to stop material falling off the bridge. |
### Chapter 6: Additional requirements to AS 5100 Bridge Design

#### Part 2: Design loads

### Part 2: Design loads

#### 10.2 Glancing collision load from road traffic

The supports for a bridge within a road reserve shall be designed to resist a minimum equivalent static load of 2000 kN which is assumed to act in any direction in a horizontal plane. The load shall be applied 1.2 m above ground level. The contact length of the load is the smaller of the contact length (for example, width of pier) or 2.4 metres. This load, in conjunction with the ultimate design dead loads on the structure, shall be considered at ultimate limit states, with a load factor of 1.0.

As this load does not represent a head on collision load for the supports that are within the clear zone (not less than 10 m), such supports shall be protected against direct impact from a vehicle travelling at an angle of less than 15° from the direction of the road centre-line passing under the bridge.

The clear zone clearance is measured from the lane line (the white line).

Note that the above Clause 10.2 stipulates that all bridge supports within a road reserve shall be designed for the minimum impact of 2000 kN regardless of the location of the bridge support.

Refer Section 13.8 for requirements for impact protection of RSS walls.

#### Protection of bridge supports within the 10 m clear zone

Bridge supports that are within the clear zone (not less than 10 m) shall be protected using a TL5 rigid road barrier for speeds greater than 80 km/h and TL4 road barrier for speeds less than or equal to 80 km/h as a minimum barrier requirement complying with the requirements of Clause 11.2 of AS 5100.2 with appropriate approach treatment. The barriers shall be designed so as to not transmit the barrier design load to the bridge supports. However, the design barrier performance level shall be determined using the barrier selection method in AS/NZS 3845 and the department’s RPDM. The design performance level of the barrier may be greater than TL5, depending on the results of the barrier selection method.

A rigid reinforced concrete barrier shall be used unless there are drainage considerations that require an open steel rail and post barrier. Appropriate foundations shall be used to limit deflections of the barrier to prevent transmission of the barrier design load to the bridge supports.

A rigid barrier is defined as having zero or extremely limited deflection, movement or yielding deformation when impacted by an errant vehicle. Examples of rigid barrier are extruded or cast in-situ concrete barrier restrained at the base. A precast concrete barrier is not a rigid barrier. Guardrail, W-beam, Thrie-beam and wire rope barriers are not permitted.

The protection barrier shall extend at least 6 m beyond the end of the protected structure in both directions, or longer if required by the risk assessment, and a transition provided to standard road barrier for continuation to the total length. For road safety requirements, the barrier alignment and total length of barrier shall be in accordance with the department’s RPDM.

#### Protection of bridge supports outside the 10 m clear zone

Acceptable barrier types are extruded concrete barriers, structural steel rail and post or G9 (modified) Thrie-beam (AS/NZS 3845) barriers for the protection of bridge supports that are located more than the clear zone of 10 m.

The selection of barrier type is subject to the results of a risk analysis, taking into account the modification factor for horizontal curve, slopes and so on in Chapter 8 of the RPDM. The minimum acceptable barrier is the G9 (modified) Thrie-beam.

Wire rope barriers shall not be used to protect bridge supports from vehicle impact.

The protection barriers shall extend at least 6 m beyond the end of the protected structure in both directions, or longer if required by the risk assessment, and a transition provided to standard road barrier for continuation to the total length.

For road safety requirements, the barrier alignment and total length of barrier shall be in accordance with the department’s RPDM.

#### Working width

Working width conditions are specified in Chapter 7 of the RPDM.
Chapter 6: Additional requirements to AS 5100 Bridge Design

Part 2: Design loads

The working width behind the barrier front face corresponds to the region where an impacting vehicle may extend during an impact (zone of intrusion) as described in AASHTO Roadside Design Guide. The motorway cross-section and alignment should be adjusted if necessary to satisfy these conditions.

The rigid TL5 barrier are to be separated from the structure by a clear gap that is large enough to ensure the barrier collision load is not transmitted to the structure. The following figure shows the acceptable arrangement of extruded barrier. Extruded barrier and its ground embedment shall be in accordance with Standard Drawing 1468 Single slope concrete barrier - Extruded median barrier - Barrier, reinforcing and expansion joint details. The minimum distance detailed is only applicable for rigid barriers.

The flare rate of the barrier (angular deviation) to the traffic lanes shall not exceed 1 in 20. The minimum width of the horizontal section at the top of the barrier shall be 150 mm for single slope concrete barrier on one face, or 200 mm for single slope concrete barrier on both faces.

Clause 11.2.1
First sentence is ambiguous. Replace first sentence with:
‘The design criteria, including loads and geometric requirements, provided in this Clause 11 (AS 5100.2) and in AS 5100.1, Clause 10 shall be used for the following.’

Clause 11.2.2
The last paragraph shall be replaced by:
Concrete barriers are rigid barriers whilst post and rail barriers are semi rigid. All loads on concrete traffic barriers shall be applied 50 mm below the top face of the traffic barrier. Where the barrier height is increased due to electrification, anti-throw and / or fire protection requirements by increasing the height of the concrete barrier, the additional barrier height is not to be modelled in the above traffic impact analysis, as it is not required for vehicle redirection. All rails on a post and rail barrier shall have the same size. All loads on rail and post type barriers shall be applied for the greater effect of:
• equal load on each rail
• the centroid of the load is greater than or equal to the minimum effective height in Table 11.2.3.

The distribution of the longitudinal loads to posts shall be consistent with the continuity of rail elements. Distribution of transverse loads shall be consistent with the assumed failure mechanism of the barrier system.

Chapter 6: Additional requirements to AS 5100 Bridge Design

Part 5: Concrete

Additional requirements to AS 5100.5 for prestressed members:
- maximum compressive stress at transfer: 0.6fcp (in accordance with Clause 8.1.4.2), and
- maximum compressive stress at all other times: 0.4f′c

Table 6.3.1
The strands referenced in Table 6.3.1 shall be replaced by
AS 4672.1 – 7 wire – 12.7 – 1 870 – Relax 2
AS 4672.1 – 7 wire – 15.2 – 1 750 – Relax 2, and
The stressing bars detailed in Table 6.3.1 shall be replaced by bars from AS/NZS 4672.1.

Clause 8.6.2(a) to (b)
Clause 8.6.2(a) and (b) are deleted and replaced by:
The crack control for flexure in prestressed beams shall be determined as follows:
a) Monolithic beams: Flexural cracking in a prestressed beam shall be deemed to be controlled if, under the serviceability limit state load combinations, the resulting maximum tensile stress in the concrete is not greater than 0.25√f′c and 0.25√f′cp, as appropriate or, if this stress is exceeded, reinforcement or bonded tendons, or both, near the tensile face shall be provided and either:
   (i) the calculated maximum flexural tensile stress under the serviceability limit state load combination, including transfer, shall be limited to:
       0.5√f′c or 0.5√f′cp or …8.6.2, or
   (ii) in the case of HLP 400 loading only, the increment in steel stress near the tension face shall be limited to 200 MPa as the load increases from its value when the extreme concrete tensile fibre is at zero stress to the serviceability limit state load combination values. The centre-to-centre spacing of reinforcement, including bonded tendons shall be limited to 200 mm.
b) Segmental members at unreinforced joints. Under all serviceability limit state load combinations, the residual compression shall be not less than 1 MPa.

Clause 10.7.3.1(a)(iii)
a) With reference to Clause 10.7.3.1(a)(iii) of AS 5100.5, when columns have been designed with N* < 0.5 ØNu, 'full' lateral restraint of longitudinal bars does not have to be provided. In such cases, columns designed with N* < 0.5 ØNu must be provided with the following minimum lateral restraints:
   • at least every sixth longitudinal bar must be restrained in accordance with Clause 10.7.3.2 to 10.7.3.4 of AS 5100.5 and the horizontal distance between laterally restrained bars must not exceed 1000 mm, and
   • all bundled longitudinal bars must be laterally restrained in accordance with Clause 10.7.3.2 of AS 5100.5.
The vertical spacing of lateral restraints must not exceed 600 mm.
b) The provisions of Clause 10.7.3.5 of AS 5100.5 for earthquake resistance take precedence over and may override above requirements.

Clause 13.3.2 Third paragraph
Replace ‘0.1Lp′ with ‘0.1Lpt′.

Appendix H Figures H1(B) and H1(C)
On all cross-sections, the bottom flange thickness is denoted as 1b. It shall be replaced by tb to be consistent with Tables H2(B)(1) & H2(B)(2).

<td>19</td>
<td>Specification of performance levels for traffic barriers including bridge rehabilitation (see Clause 10.5.1)</td>
<td>New bridges over railways to conform to railway requirements (QR documents Civil-SR-007). Retrofit barrier shall conform to both Transport and Main Roads and the rail authority criteria. For all other bridges: For new bridges, a minimum criterion is ‘regular’ to AS 5100.2. The actual level shall conform to AS 5100. However, safety in design considerations may require higher levels (for example, work taking place adjacent to barrier, hence vehicle incursion must not occur to protect the workers). For design speed equal to or in excess of 80 km/h and a radius less than 400 m, bridges shall have 1500 mm minimum height bridge barriers on the outside of the curve. For design speed less than 80 km/h and a radius less than 400 m, consideration shall be given to a bridge barrier higher than 1100 mm for concrete parapets and/or 1000 mm for steel traffic barrier to prevent overturning on the barrier and loss of side friction on the pavement. Special consideration shall be given where the speed environment transitions from high speed to a lower speed (for example, off ramps), in such cases the barrier shall be designed for the higher speed. Design of road approach barriers shall be in accordance with AS 3845 and the RPDM respectively. On widened bridges The barrier on the widened side must conform to current design requirements.</td>
</tr>
</tbody>
</table>
The barrier on the unwidened side would have been designed to the design criteria current at the time of design. The following action shall be undertaken:

Bridges with a repeated crash history of vehicle impacts or vehicles overturning shall be replaced by barriers conforming to AS 5100.

Where AS 5100 would currently require a performance level higher than ‘regular’, the bridge must be modified to provide a higher level of protection. If impractical or uneconomic, applications for a design relaxation shall be submitted to the Director (Structures Review and Standards) for acceptance.

Where a ‘regular’ level barrier or less is required by AS 5100 and the deck cannot support the current barrier design loads, a risk analysis for an existing bridge shall be undertaken in accordance with AS 5100.1 Clause 10.5.1. The minimum strength for replacement rails is 50% of ‘low’ performance level for concrete decks. If impractical or uneconomic, application for a design relaxation shall be submitted to the Director (Structures Review and Standards) for acceptance.

Note: Some existing barriers (concrete post with water pipe rails or concrete posts with balustrade) have little strength.

Replacement of barrier damaged by vehicle impact, flood or due to bridge maintenance

The original barrier on the bridge would have been designed to the design criteria current at the time of design. The following action shall be undertaken:

The barrier should be replaced with a barrier conforming to AS 5100 if the existing deck has sufficient structural capacity to support the design load.

Where AS 5100 specifies a performance level higher than ‘regular’, the deck must be modified to provide a higher level of protection. If impractical or uneconomic, applications for a design relaxation shall be submitted to the Director (Structures Review and Standards) for acceptance.

Where a ‘regular’ level barrier or less is required by AS 5100 and the deck cannot support the current barrier design loads, a risk analysis for an existing bridge shall be undertaken in accordance with AS 5100.1 Clause 10.5.1. If the bridge conforms to these criteria, a barrier of a lesser performance level may be installed. The minimum strength for replacement rails is 50% of ‘low’ performance level. If impractical or uneconomic, applications for a design relaxation shall be submitted to the Director (Structures Review and Standards) for acceptance.

<tr>
<td>27</td>
<td>Requirements for protection of bridge supports from ship collision (see Clause 11.4)</td>
<td>The Harbour Master or port authority shall recommend the type of vessel, weight of vessel and speed for impact on the bridge. This includes the channel and adjacent pier locations. The upper bound loads shall consider all vessels currently operating in the waterway or likely to operate in the waterway for the next 100 years. The minimum velocity of impact shall be the larger of the maximum of flood velocity or the speed of the vessel under power. The proposed design vessel and speed shall be reviewed by Transport and Main Roads and amended if necessary prior to acceptance by the department. The Equivalent Static Ship Impact Force in the ultimate loads shall be determined in accordance with AASHTO LRFD Bridge Design Specification. The minimum Equivalent Static Ship Impact Force applicable to piers in navigable waterways shall be determined or accepted by Transport and Main Roads. Transport and Main Roads does not permit collapse / removal of a pier provided the superstructure does not collapse as an allowable design case (paragraph 2 of Clause 11.4 of AS 5100.1 is deleted). Method of design for ship impact shall be based on one of the two following methods. 1. Energy dissipation separate from bridge The preferred option is that the energy dissipation system shall be separate from the bridge structure and spaced so that the dissipation system does not impact the bridge after deformation from ship collision. This may take the form of a fender system or an artificial island built around the pier. The fender system shall be designed as an ultimate design load case. The layout of the fender system shall be such that it guides the vessel through the bridge opening and does not have opening such that the vessel can directly contact the pier / abutment by bypassing the fender system. The artificial islands must be resilient to scour and their extent must not reduce the navigation clearance. The choice of artificial island as an energy dissipation device would be subject to the relevant environmental permit and to acceptance by the Harbour Master or port authority. 2. Impact on pier (or abutment) Transport and Main Roads may in some cases permit the provision of a combined pier / abutment and fender system.</td>
</tr>
</tbody>
</table>
Piers in the stream shall be designed for an Equivalent Static Ship Impact Force in the direction of the channel centre-line. The piers shall be designed to resist a load of half the Equivalent Static Ship Impact Force applied separately in a direction perpendicular to the channel centre-line. These forces shall be applied anywhere between 1.0 m above Mean Low Water Spring (MLWS) and 1.0 above Mean High Water Spring (MHWS).

The superstructure shall be designed to resist force equal to 20 percent of the Equivalent Static Ship Impact Force.

The bridge shall be proportioned and designed to resist above collision loads elastically. The capacities of members shall then be determined by applying the appropriate material factors to these 'elastic' member loads. The elastic capacity shall be determined using linear elastic stress strain curves and assuming that the steel stress is limited to its yield stress (0.0025 strain for 500 MPa steel) and concrete strain is limited to the strain corresponding to 0.85 times f_c (0.0011 strain for S50 concrete). The collision load may be applied simultaneously with permanent serviceability loads and 0.4 times the live load.

The following load cases shall be considered:

1.2 DL + 2.0 SDL + 0.4 (1+α) W * 1.8 *SM1600 + 1.8 PL + Ship Impact + PE or

YDL (min) DL + YSDL (min) SDL + Ship Impact

where:

- DL = Dead Load
- SDL = Superimposed Dead Load
- α = Dynamic factor
- W = Multiple lane factor
- SM1600 = Live load with or without braking
- PL = Pedestrian Load
- YDL = Dead Load Factor
- YSDL = Superimposed Dead Load Factor
- PE = Permanent Effects as defined in Clause 22.1.1 of AS 5100.2 except for Dead Loads and Superimposed Dead Loads

Note: The load combinations shall include effects to obtain the most severe loading. Serviceability thermal effects may be included if they produce an adverse effect.

Rubbing rails and fenders shall be provided to ensure no direct vessel contact on the pier / abutment.

The Equivalent Static Ship Impact Force energy dissipation model adopted in design shall be described in detail in the design report.
### Chapter 7: Matters for resolution to AS 5100

8 Tunnel design requirements

8.1 Design and construction of tunnel structures

8.1.1 Scope

The scope of this section includes:

- immersed tube tunnels
- driven tunnels
- cast-in-situ in a waterway using coffer dams
- tunnels for the cartage of dangerous goods. Such goods being transported on designated alternative open road routes, and
- bus stations and light rail stations (in tunnels).

8.1.2 Design, construction and operation criteria

This guide is supplementary to the Austroads Guide to Road Tunnels. This document takes precedence over the Austroads Guide to Road Tunnels where there is a disagreement. The following documents shall be referenced in the design and construction of tunnels:

- Workplace Health and Safety Queensland, Tunnelling Code of Practice 2007
- Australian Standard, AS 4825 Tunnel Fire Safety
- Australian Standard, AS/NZS ISO 31000 Risk Management - Principles and Guidelines
- Austroads Guide to Road Tunnels - Part 1: Introduction for Road Tunnels
- Austroads Guide to Road Tunnels - Part 2: Planning, Design and Commissioning
- Austroads Guide to Road Tunnels - Part 3: Operation and Maintenance
- Transport and Main Roads Queensland, Road Planning and Design Manual 2nd Edition: Volume 4: Road Tunnels
- British Standard, BS 8081 Code of Practice for Ground Anchorages.

8.1.3 Useful references in design and construction of tunnels

The following documents are considered useful references:

- British Standard, BS 6164 Code of Practice for Safety in Tunnelling in the Construction Industry
- UK Highways Agency, Design Manual for Roads and Bridges, Part 9, Section 2 of Volume 2, Design of Road Tunnels, BD 78/99
- Road and Traffic Authority: Road Tunnel Design Guidelines Part 1 Concept Design
- Road and Traffic Authority, Road Tunnel Design Guidelines Part 2 Development of a Scope of Work and Technical Criteria
- Road and Traffic Authority, Road: Design Guidelines Part 3 Design Development
8.1.4 Design objectives

8.1.4.1 General

a) The objectives for design and construction of a tunnel are derived from the functionality requirements of the tunnel and shall be documented in the Design Brief (may be termed the “functional specification” for detailed design).

b) Figure 8.1.4.1 identifies a range of inputs into tunnel functionality that inputs into the tunnel design objectives (some of which are further expanded upon in following sections).

8.1.4.2 Specific objectives

The specific objectives for design of any tunnel typically include:

a) Operational – To provide an internal space and environment appropriate to the functions of the tunnel.

b) Structural – To provide support for the surrounding ground for the design life of the tunnel, and to control the movement of ground water, and to prevent tunnel collapse after a fire.

c) Safety – To provide a tunnel structure that can be constructed, operated and maintained safely, such that the risk of failure or damage from all reasonably foreseeable causes is extremely remote during construction and throughout the design and operational life of the tunnel.

d) Economic – To provide a tunnel structure that minimises whole of life cost.
Chapter 8: Tunnel design requirements

e) *Role of the structure* – The tunnel structure and other structures provided undertake a variety of roles:

- to support the transport function throughout the design and operational life, and
- to provide structural adequacy to ensure fire resistance and fire separation in the event of fire.

While the first role ordinarily needs an understanding of geotechnical conditions and imposed loads to ensure a durable tunnel structure, the second role requires consideration of internal conditions to aid in the reduction of the conditions conducive to fire development, to enable detection and verification systems to function, to create appropriate separation between fire/smoke and safe areas, to prevent such safe areas becoming untenable and to prevent situations that may endanger emergency response personnel.

f) *Durability* – The tunnel must consist of components that are manufactured and/or constructed in such a manner that achieves efficiency, safety and economic requirements over the operational life.

g) *Robustness* – A tunnel structure shall not collapse due to the failure of one structural component. Tunnel facilities subject to deterioration through use and age shall be easily accessible and replaceable (for example, fans). Robustness requires that facilities that cannot be inspected, are difficult to access for maintenance and repair or replacement (for example, permanent anchors and drainage on the earth face) must be equal or more durable than the design life of the tunnel.

h) The structure shall be designed with allowance for foreseeable future development adjacent to the tunnel as per Section 8.9.1.2.

---

Failure of “one structural component” applies to any structural element including but not limited to, tunnel lining, internal support members or external ground elements required for support of the tunnel structure. Failure may occur from overloading, fatigue, fire, explosion, impact and so on. Failure of a single element must not result in damage to an extent that is disproportionate to the cause or compromise the structural integrity of the tunnel.

The actual ground conditions can vary from the assumed parameters. For any given length of tunnel that has the same assumed ground conditions, a sensitivity analysis shall be used to achieve design that is sufficiently robust to accommodate the variations.

The environmental conditions and air quality issues inside tunnels are generally more adverse compared with surface roads.

The air quality can be compromised by a high percentage of trucks using steep graded tunnels. The problem is compounded if there is an accident, vehicle breakdown or traffic congestion inside the tunnel.

Therefore, the ventilation design shall be sufficiently robust to maintain optimum functionality to meet all demands.

i) *Functionality* – Achieving the intended purpose at the required level of services is critical to a successful outcome, whether the tunnel be for transport purposes, utilities, power water supply, and so on.
8.2 Geological/Geotechnical Investigations for tunnels

a) Tunnel design differs significantly from design of plant and other structures because of the difficulty of determining accurate geological properties and the potential variability of these properties along the tunnel.

b) It is essential that adequate information is obtained from the site investigations so that the best possible information is obtained for the design. Refer to Austroads Guide to Road Tunnels, Part 1, Workplace Health and Safety Queensland’s Tunnelling Code of Practice and Work Cover NSW’s Tunnels under Construction – Code of Practice.

c) Site investigation should include but not be limited to:
   • geological modelling
   • geotechnical investigations
   • hydrogeological assessment, and
   • ground water and soil aggressive testing.

8.3 Design life – tunnels

- Permanent structural components – 100 years
- Inaccessible drainage components – 100 years
- Accessible drainage that is replaceable – 50 years
- Supports for Jet fan/major overhead equipment – 100 years
- Temporary structural components for support – 5 years
- Fans – 25 years
- Tunnel lights, sensors – 4 years
- Luminaries housing and supports – 25 years
- Cabling – 20 years
- ITS hardware – 15 years unless otherwise specified
- ITS software – 5 years
- Other electrics – 15 years
- Pumps – 10 years
- Non-structural Wall panels, doors and architectural components – 25 years
- Asphalt surfacing (if provided) – 20 years
- Non load bearing Masonry walls – 50 years
- Load bearing Masonry walls – 100 years
8.4 Durability

Durability of the tunnel structure and its associated infrastructure shall be determined by the design detail of their elements. The following criteria shall be adopted/used in the design:

a) Minimum exposure classification for cover to reinforcement shall be generally B2 to AS 5100.5 for the permanent components except for components where the design life of 50 years or less is specified in Section 8.3 shall be designed for minimum exposure classification A2 to AS 3600.

b) Also refer to Section 3.8.4 for additional requirements of concrete durability.

c) Structural design for control of cracking shall be carried out considering the exposure classification of AS 5100.5 Clause 2.8. However, in saline water, exposure Classification C shall be used.

d) Cover to reinforcement in permanent concrete components shall be in accordance to AS 5100.5.

e) The cover to reinforcement against soil in permanent shotcrete components such as facing slabs of soil nail walls or slope protections shall be increased. This cover increase shall be as per AS 5100 for components with 100 year design life or as per AS 3600 for components of 50 year design life.

f) Refer Section 8.8.3.2 for limitations in the use of shotcrete concrete.

g) Protective treatment of permanent rock anchors shall be in accordance with BS 8081 Code of Practice for Ground Anchors.

h) Protective treatment of permanent steel structural members shall be by the provision of a protective coating to achieve the 100 year design life and specified fire rating. Protective coating provided in the form of hot dip galvanising will require additional fire protection.

i) Permanent mechanical fasteners/anchors are not permitted for heavy overhead facilities (for example, jet fans), however, mechanical fasteners/anchors may be used for supporting cable trays and lights.

j) Chemical/adhesive anchor resin softens at 100°C under fire and also suffers from creep under sustain loads. Therefore, the ability of using chemical anchors as overhead fasteners to withstand all conditions, including fire and creep, shall be considered and have an appropriate design life. Chemical anchors shall not be used unless an analysis of embedment has determined that the thermodynamics of fire heat transfer of the adhesive are suitable and can withstand the effects of the design fire.

In addition to anchor capacities and durability, the resin of the chemical anchors shall be tested for fire resistance and creep deflection in accordance with European Technical Approval Guidelines (ETAG). The fire resistance requirements shall be written in the project drawings. ETAG tested displacement under sustained load protected to 100 years shall not exceed 0.2 mm/(N/mm²) in uncracked concrete at 21 to 40°C temperature range (This displacement is extrapolated to 100 years according to ETAG 001, Part 5 Section 6.1.1.2).

k) Minimum reinforcement in all blockwork walls shall be 12 mm, spaced at 200 mm maximum centres horizontally and vertically. For 50 year design life, infill grout for blockwork shall have a minimum strength of 32 MPa and 140 mm minimum block thickness (for A2 exposure
classification). For 100 year design life, infill grout for blockwork shall have a minimum strength of 40 MPa and 190 mm minimum block thickness (for B2 exposure classification).

i) For retaining walls, refer also to Section 13.2.

m) Continuous flight auger piles are not permitted for tunnels.

n) Maximum crack width in permanent concrete and shotcrete shall be 0.2 mm.

### 8.5 Dislodging of overhead equipment

Following completion of construction, the in-service performance shall be nothing that dislodges and provides a hazard to the operation of the tunnel (for example, concrete particles, fittings and so on).

### 8.6 Hydraulics and drainage

a) Tunnel portals shall have flood immunity derived from the greater of:

- The probable maximum precipitation event plus a 300 mm freeboard for climate change.
- 100 year ARI flood and a 100 year ARI storm tide (where applicable) as per the guidelines provided in department’s guideline *Storm Tide – Issues for Design of Road Infrastructure in Coastal Areas* plus 600 mm for climate change induced sea level rise (where applicable).
- Road Infrastructure in Coastal Areas plus 600 mm freeboard for climate change, and
- Highest Astronomical Tide (HAT) plus 600 mm freeboard for climate change induced sea level rise (where applicable).

b) Where the roadway geometry is such that surface water may run into the tunnel appropriate drainage is to be provided to prevent such ingress. Drainage is also to be provided to collect any rain water carried in by vehicles.

c) Drainage and any pump systems provided in the tunnel shall be designed for the worst of a 100 year ARI storm event, the requirements of any deluge system, wash down requirements or for firefighting incident management.

The department’s *Road Drainage Manual* is currently being updated. One aspect of the update will address climate change. From the most recent and relevant publications on climate change the manual mentions the following:

1. There is no definitive data to conclude an increase in rainfall intensity for storms up to a 100 year ARI event. The freeboard associated with the probable maximum precipitation will remain at 300 mm which is typical for rainfall generated flooding (for example see QUDM) and allows for uncertainties in the calculations, wave action, and so on.

2. Whilst changes in average rainfall are still relatively uncertain, a number of studies suggest increases in the intensity of the heaviest rainfall events. Some freeboard to probable maximum flood levels to the year 2100 is warranted.

3. The 600 mm freeboard associated with Coastal/HAT scenarios is an allowance for sea level rise in coastal areas. This is a projected figure to the year 2100, which aligns with a tunnel design life of 100 years).

Storm tides, HAT and climate change induced sea level rise are only applicable in Coastal Areas.
8.7 Fire and life safety

a) The design shall guarantee that the probability of an individual being exposed to a heat flux greater than 2 kW/m² or a concentration of 5 ppm CO or 1 ppm HCN or 1 ppm irritants or a visibility lower than 10 m is less than $10^{-6}$.

b) The tunnel shall be designed for an extreme case of “no collapse” in the event that any installed deluge system does not operate.

c) The following fire safety objectives shall be considered during design:
   - safeguard people from injury and exposure to toxic fumes/products due to a fire within a tunnel
   - facilitate the activities of operators and emergency services personnel
   - control and limit fire growth
   - control and limit fire spread between vehicles
   - minimise the risk of tunnel collapse resulting from fire
   - minimise the risk of flooding subsequent to a fire event
   - minimise the risk of collapse of adjoining buildings and structures as a result of fire within a tunnel
   - minimise the interruption to the operation of a tunnel resulting from a fire
   - develop a clear, reliable incident response plan to manage fire emergencies, and
   - safeguard people from the accumulation of harmful substances in a tunnel.

d) Structurally, tunnels shall provide the following in the event of a fire:
   - fire rated separation between the fire zone and the nearby areas of comparative safety, such as a cross passage or the adjacent tunnel
   - a limit to structural damage in the direct area of the fire to support response emergency services operation and emergency response, and
   - an area away from the fire, where emergency equipment continues to operate and where objects do not fall thereby making conditions safe for people trying to escape or for emergency service response efforts accessing the incident.

e) Typically, the rock / soil / concrete pillar largely creates the separation between tunnels. However fire doors in the cross passages and the walls built to house the doors will need to be designed to withstand a two hour fire. There are some situations where more onerous

---

Key references for the derivation of this sea level rise allowance are:

---

SUPERSEDED
design conditions are warranted, such as where there is the risk of tunnel collapse or inundation. These include:

- where any driven tunnel ramps cross over the main tunnels
- where the driven tunnels and shallow and significant structures above may be affected
- in cut and cover tunnels where significant structures above may be affected
- intermediate floor/roof levels in multilevel cut and cover sections
- in water bearing ground, and
- where failure of the lining would allow in inrush of water in significant quantities which could not be practically controlled by pumping.

f) In situations such as listed in Section 8.7 c), a secondary lining using a suitable passive fire protection material would be required. Further geological investigations are required to determine the passive resistance provided by rock and soil materials, particularly in areas of poor sub-surface materials.

g) Design for fire and safety shall be in accordance with AS 4825 *Tunnel fire safety*.

*Figure 8.7 – Tunnel safety inputs*

The design fire shall be:

- for road tunnels, a fast to ultra-fast growth rate to a PHRR of 100 MW fire with a sensitivity case of 120 MW
- busway tunnels shall be designed to withstand a fast to ultra-fast growth rate to a PHRR of 30 MW fire with a sensitivity case of 40 MW, and
- light rail tunnels shall be designed for a RABT-ZTV (train) fire curve.

h) The structural integrity of the tunnel shall remain intact after the fire. Structural fire resistance minimum is to be 120 minutes of ISO curve for non-critical locations, and 120 minutes of hydrocarbon fire for critical components. Where ISO fire applies, structural design shall comply with AS 3600 *Concrete Structures provisions*. Where hydrocarbon fire applies, passive protection shall be provided to the supporting structural components in the proximity of the fire to limit the maximum heat rise at concrete surface to 380 degrees for the specified duration.

i) The tunnel shall provide emergency “cross passages” or other emergency exist passages with a spacing not exceeding 120 m with fire safety doors allowing direct emergency exit.

j) The tunnel shall be designed for an extreme case of a “no collapse” case in the event that any installed deluge system does not operate.
k) Plastic reinforcement bar chairs are not permitted as, in the event of a fire, they melt and thus allow heat transfer to prestressing materials and reinforcement.

8.8 Design criteria

8.8.1 General

Tunnels shall conform to the following criteria:

a) When the top surface of the tunnel roof forms part of a road or busway, this section of the tunnel shall be designed for one of the following four options:
   - The worst combination of tunnel and bridge design criteria (for example, cast-in-place piles for a bridge may be the controlling criterion).
   - Interconnected reinforced concrete secant pile with a minimum diameter of 900 mm.
   - 1200 mm diameter cast-in-place piles with maximum spacing of 2.5 times the pile diameter installed in accordance with Technical Specification MRTS63 Cast-In-Place Piles when an inspection shield is required. The space between the piles shall be connected with a reinforced concrete arching system that has a drainage layer behind it.
   - 900 mm diameter cast-in-place piles with maximum spacing of 2.5 times the pile diameter installed in accordance with Technical Specification MRTS63 Cast-In-Place Piles when no inspection shield is required. The space between the piles shall be connected with a reinforced concrete arching system that has a drainage layer behind it.

b) A theoretically drained tunnel designed without hydraulic head is not permitted. The minimum head shall be based on the higher of:
   - the predicted, permanent water table
   - 2/3 of the tunnel height, with the full tunnel height as a sensitivity test, or the finished external surface level if lower, or
   - 30 kPa.

c) All cut and cover tunnels in road reserve or under public space shall have a 100 mm thick reinforced concrete protection slab constructed above the tunnel.

d) Tunnels shall be designed for asymmetric load transfer and asymmetric hydraulic head of water.

e) If the height of cover over the tunnel crown is in material capable of arching, and is less than the width of the tunnel, a detailed analysis of arching shall be undertaken.

f) Design of concrete shall consider concrete shrinkage and temperature effects.

g) Any concrete ceiling to separate traffic from air ducts shall be supported on concrete corbels.

h) All permanent structural fittings/anchors shall have 100 years minimum Design Life. Grade 316 stainless steel complies with this requirements.

i) The outside of the tunnel lining is to be provided with a drainage layer and waterproof membrane. Where this cannot be installed due to construction technique, for example, TBM construction, alternative and equally effective waterproofing measures have to be developed and submitted for departmental approval.
j) No water shall leak from the tunnel or wall, or drip from the tunnel soffit onto the tunnel road surface.

k) Long-term concrete modulus relevant for deflection calculations shall be used.

l) Any property acquisition and areas required for easements, including those to mobilise the soil block for ground anchors, soil nails, rock bolts, and so on, shall be determined.

m) The Designer shall produce resumption and easement plans to identify the tunnel in regards to permissible future development above the tunnel.

n) Geometric design, pavement design, visual amenity, drainage design, ventilation design, lighting design, electrical supply, monitoring and control, services and plant rooms shall be in accordance with Austroads Guide to Road Tunnels – Part 2: Planning, Design and Commissioning.

8.8.2 Road and bus tunnels – additional requirements

a) For road and bus tunnels, traffic barriers in tunnels shall be a minimum of 1100 mm high, single slope concrete barriers.

b) The geometric constraints of tunnels mean that the Designer shall ensure that the geometric shape of the tunnel and (decorative) wall panels is such that errant vehicles do not contact the tunnel or wall panels after they have impacted the barrier. Working width shall be in accordance with the Austroads Guide to Road Tunnels Part 2. Treatment at tunnel entrances, approaches, merges and diverges, shall be in accordance with Road Planning and Design Manual 2nd Edition, Volume 3, Part 6. Also refer Chapter 6, Part 2: Design Loads, Section 10.2 of this document.

c) The confined space of the tunnel must be adequately considered when designing for crash cushions.

d) The geometric shape of a tunnel poses additional risks that are required to be protected by barriers. These shall include:
   • protecting the tunnel and other infrastructure from being impacted by vehicles
   • reduced sight distances on curved sections, and
   • reduced lateral clearances.

e) Special consideration needs to be made to the use of work cushions at entrances / approaches / merges and diverges.

8.8.3 Design criteria – driven tunnel

8.8.3.1 Tunnel Boring Machine (TMB) tunnels

Fibre reinforced precast concrete single pass segmental linings are permitted in TBM driven tunnels.

8.8.3.2 Tunnels with two pass lining system

Driven tunnels shall conform as follows:

a) Design of concrete shall consider shrinkage of concrete, and temperature (ordinal and differential) effects.
b) Symmetric and asymmetric loads are to be considered for design of primary and secondary tunnel lining.

c) Cast insitu reinforced concrete secondary lining is preferred. If cast insitu unreinforced secondary lining is proposed, the designer shall demonstrate that the concrete arch remains in a serviceable state and in compression throughout the life of the tunnel. The designer shall take into account the tunnel geometry, concrete shrinkage and creep, corrosion of canopy tubes and rock bolts and changes to water table as well as future developments. Unloading effect created by the excavation of basements for future development adjacent to, or on top of the tunnel shall also be included in the tunnel design. The design shall be provided to Transport and Main Roads’ Director (Structures Review and Standards) for review and acceptance.

d) Shotcrete to cover reinforcement bars in tunnel secondary lining is permitted in situations where there are variations in the tunnel geometry such as transition sections, Y junctions and fan enlargements, shotcrete is permitted subject to meeting departmental requirements for design life, durability, fire resistance, water tightness and robustness and resistance to accidental damage.

e) However, there may still be the cases such as junctions where heavier steel reinforcing bars are required. In those cases good workmanship shall ensure that the steel is safely encased in dense concrete with a low permeability and cast insitu concrete is required.

f) Sprayed waterproof membranes are permitted provided appropriate quality assurance measures are undertaken.

The following definitions apply to two pass lining system in driven tunnels:

- **Primary Lining**: when the tunnel is sequentially excavated, ground support in the form of shotcrete, usually with lattice girders and reinforcement is installed as excavation proceed.
- **Secondary Lining**: after installation of the primary lining, at a later stage a cast-insitu concrete lining is installed. This is called the secondary lining.
- A drainage fabric or water proofing membrane is sandwiched in between the primary and the secondary linings.

### 8.8.4 Design criteria – cut and cover tunnel

Cut and cover tunnels shall conform as follows:

a) The cut and cover tunnel shall be designed as undrained.

b) The tunnel roof and connection to the walls shall be coated with a water proofing sheet membrane.

c) Cover to concrete shall be in accordance with AS 5100.

d) The minimum exposure classification for cover of concrete members shall be B2. Structural design for control of cracking shall be undertaken, taking the exposure classification of AS 5100.5 Clause 2.8 into account.
e) The exterior walls and deck shall be integral. Bearings are not required under deck units if they are used in the roof.

f) Contiguous piles shall have a minimum diameter of 600 mm.

g) A drainage layer shall be provided behind the walls.

### 8.8.5 Parametric study

A parametric study shall be undertaken on the sensitivity of the tunnel design to the adopted design loads and assumptions.

### 8.9 Design loads

#### 8.9.1 Live loadings

Live loadings above tunnels, on surface of Tunnel Portal Transition Zones, and within Easement Areas shall be in accordance with Section 8.9.1.1 to 8.9.1.3 as appropriate.

##### 8.9.1.1 Vehicle live loads – to be applied anywhere in the road corridor

a) Live Loadings shall be limited to SM1600, HLP 400, W80 and A160 in accordance with the requirements of Australian Standard AS 5100 and the vehicles in Figure 8.9.1.3.

b) Crane loading:
   - It is desirable that crane outrigger loads must not exceed other additional loads listed in Section 8.9.1.3.
   - However crane loads are project specific and shall be nominated by the Design Engineer.
   - The maximum outrigger load, outrigger spacing and minimum rigid bearing area shall be specified by the Designer.

##### 8.9.1.2 Other additional loads due to development above and/or beside tunnel

The maximum future development load permitted on top of the tunnel shall be the larger of (a) and (b):

a) Loading due to permitted development above consisting of 50 kPa acting on the surface level in the case of driven tunnel and cut and cover tunnel.

b) Any loads from foreseeable future permitted developments above and/or beside the tunnel.

Maximum surcharge permitted is the natural surface level build-up of up to 1 m with fill equivalent to a uniformly distributed load of 20 kPa.

Hence the “other additional loads” consists of future development load plus the surcharge load outlined above.

The permitted maximum excavation on top or either side of the tunnel shall be 1 m.

The tunnel designer shall provide a performance specification on what allowable movement is acceptable to the integrity of the tunnel, where additional stress or load can be applied or tolerated.

##### 8.9.1.3 Tunnel structure retaining wall design loads

a) Fill maximum surcharge of 20 kPa (1.0 m depth).

b) Live load surcharge load behind retaining walls to be applied as 25 kPa uniform surcharge in accordance with AS 5100.2.
**Figure 8.9.1.3 – Design vehicles live loads above tunnels**

8.10 Structural design

Structural members shall be designed in accordance with:

- AS 3600 for concrete members with a 50 year design life
- AS 5100 for concrete members with a 100 year design life
- AS 4100 for steel members, and
- BS 8081 for rock anchors.

8.11 Mechanical and electrical services and ITS

The tunnel design shall accommodate the provisions of AS 61508 Functional safety of electrical/electronic/programmable electronic safety-related systems and ITS.

8.12 Review of drawings and scheme documents

The drawings and scheme documents are to be reviewed and accepted for safety, durability, future performance, constructability and maintenance by Transport and Main Roads in accordance with design management (generally reflecting a 15%, 85% and final design stages) and any permission to use (PTU) requirements of the Contract.

a) The following documents shall be submitted to the department for review:

- Design Report as per Clause 8.13
- Fire and Life Safety Report (minimum requirement is a copy of submission to Queensland Fire and Rescue Service (QFRS)
- Operation, Structures Inspection Manual
Chapter 8: Tunnel design requirements

• Incident Management and Recovery Manual, and
• Level 2 (and Level 3 if required) Tunnel Inspection Report.

b) All reports and manuals shall be submitted and accepted by Transport and Main Roads in accordance with the Contract prior to opening the facility to use. All procedures / trials / simulations / tests / training are to be satisfactorily completed prior to opening the facility to use.

8.13 Design report

a) A Design report shall be prepared and provide details including, but not limited to:

• Transport and Main Roads publication design criteria / codes used, including date of publications and (any) amendments
• date of referenced Transport and Main Roads Design Criteria for Bridges and Other Structures (date of this document stated on the first page of this attachment)
• other referenced documents
• design criteria adopted, including those from other jurisdictions / regulatory authorities / stakeholders
• the design methodology, durability, serviceability and ultimate loads, together with a statement of the design life for each structure and each component category (drainage, signs, metalwork, mechanical, ITS, asphalt, architectural components and so on)
• controls / limits / restrictions / assumptions
• construction methodology for the design developed
• durability and robustness
• “Safety in Design” considerations for construction, inspection, maintenance and operation
• achievement of functionality
• achievement of Level Of Service (LOS), and
• assumptions, departures, Extended Design Domain (EDD).

b) The report shall demonstrate compliance with the project Design Brief. Any proposed departures / relaxations / exemptions from the Design Brief shall be discussed in terms of safety, durability, future performance, constructability, operations, maintenance and whole-of-life cost considerations. Any proposed departures / relaxations / exemptions shall be submitted to Transport and Main Roads Director (Structures Review and Standards) for consideration in accordance with the contract. The Design Report shall be certified by the appropriately experienced RPEQ responsible for each component of the design.

c) The final Design Report shall be submitted as part of the final scheme submission for Transport and Main Roads acceptance. For Alliance / Early Contractor Involvement (ECI) / Design and Construct type projects, the Design Report shall be accepted by the department prior to construction commencing.
8.13.1 Incident management and recovery manual

An Incident Management and Recovery Manual shall be prepared and shall include, but not be limited to:

- vehicle breakdown
- damage-only incident
- debris on road
- fire
- injury incident
- spills
- load shedding
- over-height vehicles
- external electrical supply failure
- water on pavement
- flooding
- unauthorised entries
- explosion and release of noxious liquid or gas, and
- incident management training (including any in-tunnel incident trials/simulations/tests).

8.14 Construction

8.14.1 Construction Specifications

a) Supplementary Specifications for tunnel concrete and shotcrete shall be in accordance with Transport and Main Roads requirements.

b) Concrete shall conform to the requirements of Transport and Main Roads Specification MRTS70 Concrete for alkali silica reactivity assessment.

c) Tunnel construction shall conform to Transport and Main Roads Specifications MRTS03, MRTS04, MRTS06, MRTS71, MRTS72, MRTS73, MRTS74, MRTS75, MRTS78, MRTS78A, MRTS79, MRTS91, MRTS93, MRTS94, MRTS228 and MRTS256 and the relevant Transport and Main Roads Intelligent Transport Systems Specifications.

d) The Contractor’s working method and system shall be designed to control ground water. Removal of ground water by the Contractor shall not be undertaken in such a manner as to cause damage to any existing development or structure and the tunnel.

e) Significant lowering of the natural ground water table shall be avoided where practical. Any changes in natural groundwater shall be subject to Environmental Impact Statement (EIS).

f) The Contractor shall install piezometric devices to monitor seasonal fluctuations in ground water between the tunnel and any existing development or structure.
8.14.2 Instrumentation

The Contractor shall install thermocouples in concrete linings to monitor the response of the concrete. Shrinkage testing of the actual concrete shall be undertaken to confirm the actual performance of the concrete.

8.14.3 Design validity check during construction

a) The design assumptions must be validated during construction.

b) Testing or other physical assessment is required to ensure that any drainage liner has not been crushed or otherwise damaged during construction.

8.14.4 Validation of permanent anchors

a) Service Life Performance.

Acceptance testing for Service Life Performance are:

i) For the purpose of production testing of permanent bolts installed in the Works shall be split into lots of 1000 bolts, or otherwise by the Designer.

ii) Ten out of a lot of 1000 bolts, or a similar proportion approved by the Designer, shall be randomly selected after installation for production testing for acceptance of service life performance.

iii) The following properties of the corrosion protection system shall be inspected, photographed and measured where appropriate. The bolt shall be sectioned to obtain the following data:
   - integrity and thickness of cement grout cover
   - location and spacing of cracks in cement grout, and
   - degree of filling the grout inside and outside the sheath/sleeve.

Overcoring shall be carried out in the following manner. A diameter of 150 mm hole shall be cored over the bolt. The core shall be diamond sawed into two half cylinders for inspection. The over cored hole shall be immediately filled with cementitious grout and or another bolt.

The anchor has failed if the test shows the bolt is not fully encapsulated in grout irrespective whether the defect is observed in the inner or outer grout annulus or if other grout defects are observed such as excessive cracking of the grout which may affect the service life of the bolt or if the sheath has been punctured.

The anchor will be accepted if the test shows the bolt is fully encapsulated in grout and does not show any other defects such as excessive cracking which may affect the service life of the bolt.

iv) Production tests for service life performance shall be carried out on one percent of the permanent rock bolts installed. The Designer will select the bolt which shall be recovered by over coring.

v) Mandatory Testing shall be carried out in all lots however if the criteria of test reductions is met, the minimum for mandatory testing shall be for Lot 1 and 2 as in Lot “X” and Lot “Y”. Lot “X” and “Y” will be selected by the Designer during construction.
Acceptance criteria for Service Life Performance are:

i) Production test series for service life performance shall be conducted on 10 out of 1000 bolts per lot. The lot shall be accepted if not more than one bolt out of ten recovered by over coring shows defects.

ii) The lot shall be rejected if more than one fails out of ten. Subsequently another 10 bolts shall be tested in the lot as directed by the Designer until the failure rate within the lot drops below or is equal to 10%.

Acceptance criteria for reduction of production testing for Service Life Performance are:

i) Testing by overcoring into other lots shall continue until the cumulative average number of grout defects becomes less than 3%. Testing may then be terminated until mandatory testing commences again at Lot “X” and “Y”.

ii) The following tables illustrate three examples for acceptance testing in regard to service life performance with the main focus on the acceptance criteria within a lot and the accumulated average criteria for a reduction of production testing.

Table 8.14.4.3(a) – Acceptance testing for service life performance – Example 1

Testing will be terminated in each lot once the acceptance criterion in a lot falls below or is equal to 10%. Testing will continue across into other lots until accumulated average falls below 3% however mandatory testing will continue in Lot “X” and Lot “Y”.

   a) 10% of all rock anchors shall be proof tested to the serviceability load.

   b) The design and construction shall allow for extra rock anchors in excess of the design number for long-term durability monitoring/testing at the rate of 2 per 1000 or part thereof.

8.15 “As Constructed” drawings and construction handover report

Refer MRTS50 Specific Quality System Requirements and Drafting Design Presentation Standard Manual Volume 3: Chapter 1: Introduction.

8.15.1 Fire and life safety report

Minimum requirement is the submission of Operation, Inspection and Maintenance Manual to the QFRS.

   a) An Operation, Structures Inspection Manual shall be prepared as a part of the Designer’s Safety in Design obligations under the relevant act and regulations. The manual relates to in-service inspection, maintenance and operation of the tunnel.

   b) The Operation, Structures Inspection Manual shall include but not be limited to:

      • Operational information on all structures and equipment (mechanical, electrical, ITS, and so on).

      • Inspection frequency. (For typical bridges, this will be in accordance with the Transport and Main Roads Structures Inspection Manual. For special/non-routine design, the frequency needs to be developed.).

      • Operational requirements.

      • Inspection frequency. (For tunnel structures special/non-routine design, the frequency will need to be developed.).

      • Details of inspection access requirements (including any confined space access requirements).

      • Design life of all components and sub-components. For any component or sub-component that has a design life less than the specified design life of the structure, details for replacement of the (sub-) component shall be provided.

      • Routine maintenance schedule, including cleaning, wash down, failed light replacement, incident response systems testing, and so on.

      • Scheduled maintenance program, incorporating procedures for maintenance including replacement schedules. For paint systems, the procedure shall be suitable for repainting by roller or brush without abrasive blasting to bare metal. The recoat system shall be suitable for over-coating the previously applied system.

      • Details of how routine and schedules maintenance will be undertaken, and

      • Special maintenance.
8.15.2 Level 2 (and Level 3) inspection of tunnel

a) A Level 2 (and Level 3 if required) inspection shall be carried out by a Transport and Main Roads certified / qualified inspector prior to opening of the facility to use in accordance with the department’s Structures Inspection Manual and the results provided to the department for entering into Transport and Main Roads Bridge Information System.

b) Structure and Design inventory verification forms shall be completed.

8.15.3 Learnings

The projects shall identify in the documentation any learnings for possible application to future projects.
9 Development application in the proximity to tunnels

9.1 Purpose

The purpose of this chapter is to provide guidelines on the type of information the department requires for assessing the impacts of the proposed developments in the proximity to tunnels. This document also stipulates the technical requirements for compliance at the design and construction stages of the development.

9.2 State-controlled tunnels in south east Queensland

The tunnels constructed and planned within the state transport network are either cut and cover tunnel or driven (mined) tunnel. State owned busway and road tunnels are listed below in Table 9.2.

Table 9.2 – State-controlled tunnels¹ (as at Jan 2016)

<table>

<td><strong>Driven Loading</strong>: 50 kPa at 1 m above the tunnel crown, and up to 1 m of surface fill (20 kPa). <strong>Driven Unloading</strong>: Up to 7 m below natural surface to within 7 m of the driven tunnel roof or sides. <strong>Cut and cover loading</strong>: 25 kPa with a load factor of 1.5. <strong>Cut and cover unloading</strong>: varies depending on location.</td>
</tr>
</tbody>
</table>

**Notes:**
1. Excludes: Clem 7 and Legacy Way tunnels; Transport and Main Roads is not the asset owner of these two tunnels.
2. Refer to IDAS trigger mapping for location.
3. Airport Link tunnel will be state-controlled asset at the end of 40 year franchise with Transurban.

The loading and unloading specifications have been included in Table 9.2 as a guide for adjacent developments. Detailed loading and unloading specifications are available for each tunnel and will be made available on request.

The information provided in Table 9.2 is obtained from the as-constructed tunnel drawings and may not be reflected in the easement documents associated with the tunnel.

**9.3 Development Approval Requirements**

The impacts of development on the tunnel will vary depending on whether the development abuts an existing or future tunnel.

**9.3.1 Zone of Influence for Tunnels**

**9.3.1.1 Driven / Bored Tunnels**

a) For development involving proposed construction adjacent to a Transport and Main Roads bored tunnel, the lateral zone of influence distance \(Z\) as shown in Figure 9.3.11 from the extreme perimeter of tunnel structure which trigger the need for Transport and Main Roads review shall be the greater of:

- 25 m
- \(W/2 + D_t\)
- \(D_t + D_h\)
- \(W/2 + D_c\) or
- 2\(D_c\)

Where:

- \(W\) = Tunnel width
- \(D_h\) = Tunnel depth
D_t = Depth to tunnel extrados from the ground level
D_c = Depth of excavation for adjacent new development
Tunnel protection zone = 2 x Z + W.

Figure 9.3.1.1 - Lateral zone of influence for driven tunnels

b) For multiple bored tunnels, this clearance distance is as above.

c) Where clearance envelopes for two tunnels or more overlap, all proposals shall be referred to Transport and Main Roads for acceptance.

9.3.1.2 Cut and cover tunnel

For new developments adjacent to State-controlled cut and cover tunnels, the lateral distance from the tunnel outer face which trigger the need for departmental review shall be the greater of:

- 10 m, or
- lateral offset from the tunnel outer face equal to the depth from the driving surface of the tunnel to the ground level.

9.3.2 Permissible excavation above and beside a tunnel and within the easement area

9.3.2.1 Bored tunnel

a) No provision for development above and adjacent to a tunnel.

For tunnels that were not designed to accommodate future development, the following conditions shall apply:

- no excavation permitted on top of the tunnels, and
- excavation adjacent to tunnels is permitted subject to agreement with the department’s Deputy Chief Engineer (Structures) and the applicant (Developer) shall carry out tunnel impact studies (Table 9.3.3) to confirm no adverse impact on the integrity of the tunnels.

b) Provision for development above and adjacent to a tunnel.

Excavation above and adjacent to tunnels shall comply with the permissible condition for excavation stipulated by the tunnel designer and/or the department. Excavation shall not
extended into the minimum cover above the tunnel roof as specified by the tunnel designer and/or the department.

c) Provision for development on easement support area.

Excavation and development loading on easement area shall comply with the easement support conditions of the relevant tunnel.

9.3.2.2 Cut and Cover tunnel

a) Above the Tunnel.

Excavation shall not extend into the easement boundary above the tunnel roof or into the 0.5 m cover above the tunnel roof, whichever provides the most cover above the tunnel.

b) Beside the Tunnel and in the Transition Zone from the Surface to the Tunnel Portal.

Excavation shall not extended into the easement boundary beside the tunnel or into the 0.5 m side cover from the sides of the tunnel, whichever provides the most side cover beside the tunnel.

From the natural surface level to a depth of no greater than 3.5 m, or if tie back anchorages are present a Transport and Main Roads’ review is required.

9.3.3 State-controlled future tunnel assessment requirements

a) Where a development is proposed adjacent to or above a future tunnel, the development shall be reviewed by the department using the available information for the proposed tunnel design, current at the time of the application. The impacts of development adjacent to a future tunnel will depend on:

• the height and depth of the development
• the proximity of the development to the tunnel
• the type of future tunnel it is adjacent to i.e. cut and cover or driven tunnel, and
• geotechnical considerations.

b) The departments design specifications for future tunnels are discussed in Section 8. Proposed development shall not compromise the future tunnel such as by adverse loading or excavation adjacent to the future tunnel location. In order to determine the impact of the proposed development on the design and constructability of the future tunnel the following information (Table 9.3.3) is required for assessment:

• The assessment of development impacts on future tunnels will be undertaken on a case by case basis and will also relate to the planning and design undertaken for the project.

• To demonstrate compliance with any conditions imposed as part of a concurrence agency response, the applicant shall be required to provide RPEQ certified detailed geotechnical report and RPEQ certified detailed engineering drawings and supporting technical documentation to demonstrate that the design and construction of the future tunnel will not be compromised.
Table 9.3.3- State-controlled future tunnel assessment requirements

<table>
<thead>
<tr>
<th>Activity</th>
<th>Information Required</th>
</tr>
</thead>
</table>
| RPEQ Certified structural engineering design drawings | Structural engineering design drawings for the development, including cross sections/elevations and any required supporting technical details, shall be provided which clearly show the following in relation to the future tunnel:  
• the location and setback of the proposed development (including the outermost projections of the closest structural elements such as retaining structures and building foundation structures) from the future tunnel  
• the type, spacing, location and depth of building foundation structures (including any proposed structures such as footings, and bored piles/piers and associated columns)  
• the proposed retention system for the development, including the location, length, depth and angle of insertion of any proposed shoring, rock anchors and/or soil nails. Both the temporary and permanent retention design for the excavation should be detailed  
• demonstrate any proposed shoring, rock anchors and/or soil nails will not compromise the future tunnel both during construction and on-going operation, including any structural or geotechnical impacts, and  
• demonstrate that the lateral and vertical loading implications of the proposed development will not compromise the safety and operational integrity of the tunnel. The loading configuration of the proposed development should be provided. |
| RPEQ Certified Geotechnical investigation report | Preliminary geotechnical design information on the following, amongst other relevant considerations, to inform the structural engineering design and construction management of the development:  
• earthworks, including methods for the excavation, the excavation and drilling of rock, the stability of open excavations, and filling/back filling and compaction  
• permanent and temporary basement retention options, design loads and geotechnical design parameters  
• suitable options for foundation structures, design loads and geotechnical design parameters  
• groundwater management  
• vibration impacts from drilling, boring and excavation, and  
• advice on effects on the existing state transport infrastructure and relevant construction issues. |

9.3.4 State-controlled existing tunnel design assessment requirements

As noted in Table 9.2 each state-controlled tunnel has been designed to a range of specifications to suit transport requirements and localised geological conditions. The assessment of development impacts on tunnels will be undertaken on a case by case basis and will depend on the circumstances of the site and nature of the proposed development. Development proponents are encouraged to contact the Department of Infrastructure, Local Government and Planning to request a pre-lodgement meeting where development may impact on a state-controlled transport tunnel.

Table 9.3.4 details information that may be requested by the department to allow Transport and Main Road’s Engineering and Technology Branch to assess the impact of the proposed building design on the existing tunnel.
Table 9.3.4 – State-controlled existing tunnel design assessment requirements

<table>
<thead>
<tr>
<th>Activity</th>
<th>Information Required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Proximity to State-Controlled Tunnel</td>
<td>Scaled and clearly labelled layout plans, elevations and cross sections shall show the Location and minimum setback of all levels of the proposed development (including building foundation and retaining structures) in relation to the tunnel (considering 3D space) and to the volumetric boundary of the existing tunnel. These details shall be accompanied by figures/sketches which detail the as-built details of tunnel infrastructure (including any retaining structures), including relevant dimensions in plan and section view. The minimum distance between tunnel external wall/tunnel crown and the closest structural element of the new development shall be clearly shown.</td>
</tr>
</tbody>
</table>
| Geotechnical studies | RPEQ certified detailed geotechnical investigation report for the structural engineering design and construction management of the development, addressing the following, including other relevant considerations:  
• earthworks, including methods for the excavation, the excavation and drilling of rock, the stability of open excavations, and filling/back filling and compaction  
• permanent and temporary basement retention options, design loads and geotechnical design parameters  
• suitable options for foundation structures, design loads and geotechnical design parameters  
• groundwater management  
• vibration impacts from drilling, boring and excavation, and  
• advice on effects on the existing state transport infrastructure and relevant construction issues. |
| Imposed load assessment | The applicant to provide an accurate ‘run-down’ of the building loads due to new development up to the foundation level and check that the resulting bearing pressure does not exceed the allowable design loads as per the relevant tunnel design criteria. This assessment including appropriate calculation shall be certified by Applicant’s RPEQ. |
| Impact Assessment Report | • A RPEQ certified impact assessment report including predicted movements and vibration on the existing tunnel and any associated retaining structures due to the construction activities associated with new development. This assessment is necessary to demonstrate that the proposed retaining system (for an excavation) and the construction methodology are appropriate to keep the tunnel movements within the allowable limit given in Section 9.4.7.  
• The impact assessment must include 3D or 2D Finite Element Modelling at all critical sections. The modelling undertaken shall be based on a detailed geotechnical investigation. |
| Foundation details | • Building foundation detailed plans / general arrangement drawings  
• Layout plan showing footing soffit reduced levels  
• Footing type  
• Dimensions  
• Loading configurations and approximate loads (refer Table 9.3.5 for load calculation requirements). |
| Adjacent foundations | Edge / perimeter loading details from adjacent buildings approved post state-controlled tunnel construction. |
| Building Framing Elements | • Details of building columns and lift core  
• Column and lift core loading |
### Activity Information Required

** Temporary and permanent retention system**

- Details of retention structures – anchors temporary and permanent

**Construction and Excavation**

- Construction work method statement shall address the following:
  - details of excavations, filling/backfilling / compaction, filling method statement – the applicant must fully detail any excavation or compaction as these will change the applied loads and confirm these do not exceed those specified by the department
  - support details: details of basement excavation support (if relevant), including any temporary support requirements and the potential loading of these support elements on the existing tunnel
  - retention / temporary support / anchor arrangements
  - loading on retention elements such as anchors
  - exclusion zones
  - total duration of temporary retention system until permanent strutting is constructed (e.g. basement floors) for retention system
  - machinery used – construction loading shall be considered, the use of storage materials, the use of heavy vehicles must be considered
  - vibration issues – proposed piling system shall be assessed to determine if the impact on the tunnel is acceptable; generally bored piling systems are preferred as driven piles could induce significant stresses and vibration that might affect the tunnel structure or function, and
  - assessment of any construction related vibration.

### 9.3.5 Building load calculations

Building load calculations of proposed developments shall include a floor by floor summary. Slab thickness, dead and live load values shall be determined in accordance with AS 1170.1 and shown in summary. An example of a summary of a building load calculation is shown on Table 9.3.5.

**Table 9.3.5 – Building load calculation**

Existing building(s) adjacent to proposed development and existing tunnel might have used some of the allowable loading on tunnel. Therefore, the applicant is required to determine the combined building loads of both proposed development and adjacent building(s) and confirm these combined load are not exceeding the allowable loading on tunnel.
9.4 **Pre-construction, construction and post construction compliance requirements**

a) The department is responsible for safeguarding the tunnel infrastructure and to ensure that the proposed new development has no adverse impacts on the integrity of the tunnel. The safety of the travelling public is paramount and the tunnel safety cannot be compromised at any time due to any large or small construction activities adjacent to a tunnel.

b) Prior to commencing work, the development proponent shall have a prestart meeting with the department to discuss the construction methods and program, tunnel monitoring - trigger and alarm levels, and any matters requiring reporting of changed conditions or the need to stop work until a safety assessment is completed. Site meetings to discuss progress and issues shall be held not less frequently than monthly.

c) Any damage to the tunnels caused by the development shall be rectified by the developer at his own cost.

d) The department may impose some or all of the following activities to the proposed development:
   - potholing to confirm tunnel depth
   - demolition risk assessment and method statement
   - foundation survey depth confirmation
   - dilapidation survey: pre and post construction, and
   - monitoring: crack, movements / tilts (tunnel and retaining walls), ground movement substrate movement (inclinometers), vibration and ground water.

9.4.1 **Potholing**

Where a development is proposed in close proximity above a tunnel (within three metres) the department may require potholing to confirm the actual location of the tunnel roof protection slab. A sketch plan of the proposed potholing positions and potholing machinery to be used (including vehicle loads) shall be forwarded to the department for review and approval prior to the commencement of potholing works. Potholing positions shall be confirmed on site by a registered surveyor and a sketch plan of the tunnel depths shall be forwarded to the department after completion of the potholing works.

9.4.2 **Demolition: risk assessment and method statement**

a) Prior to commencement of any demolition activity, the contractor shall undertake a Demolition Risk Assessment of the potential damages to departmental structures and tunnels. Temporary measures shall be provided to prevent damages to departmental assets during demolition.

b) The department may request for a Demolition Method Statement upon the outcome of department’s review of the demolition risk assessment. This statement shall include proposed monitoring locations for displacements, existing cracks and any other measurable impacts to departmental structures during demolition.

c) If demolition is deemed high risk to departmental assets, the department may request controlled demolition procedures to be overseen by departmental compliance officers.
9.4.3  Foundation excavation survey

a) Where a development is constructed within three metres above / adjacent to a Transport and Main Roads tunnel, the department may request a Foundation Survey Sketch Plan to be prepared. A Foundation Survey Sketch Plan shall be prepared at the completion of footing excavation and prior to foundation concrete pour. The sketch plan shall be prepared by a registered surveyor and shall compare the design excavation levels to the as-construction excavation levels. Where the foundation includes piled walls, the surveyor shall provide confirmation the as-constructed pile depths.

b) If the as-constructed levels are within 100 mm – 200 mm of the design excavation levels, the department will issue an approval to proceed. If excavation exceeds permitted tolerances the developer shall undertake satisfactory compliance activities and reissues a Foundation Survey Sketch Plan showing compliant excavation levels.

9.4.4  Tunnel dilapidation survey

a) No demolition, excavation or construction shall commence prior to department’s acceptance of the dilapidation survey. A dilapidation survey is required for all types of tunnels and all types of development with or without basement.

b) The tunnel dilapidation survey shall be carried out by the Developer prior to demolition, excavation and construction work. The survey shall assess the tunnel’s current structural condition and shall record all existing cracks and other defects. Photographs shall support the dilapidation survey. An appropriately experienced RPEQ engineer shall carry out the dilapidation survey, which is carried out with the consent and in the presence of a departmental representative. A copy of the dilapidation survey shall be given to the departmental representative not less than five working days before any works that cause vibration or alter local stresses in foundation materials. The dilapidation survey shall be undertaken no more than six months prior to commencement of work.

9.4.4.1  Driven tunnel survey duration

a) Transport and Main Roads requires inspection of the tunnel lining (the secondary layer) on a monthly basis and compare with the initial dilapidation survey during the excavation stage of the basement bulk excavation and thereafter dilapidation surveys are required at the following stages:
   - end of bulk earth work basement excavation
   - completion of basement work – “close off” of basement ground level slab, and
   - end of the construction work.

b) Early termination of dilapidation survey is at the discretion of the Director (Structures Review and Standards) in the event of no change in tunnel behaviour.

9.4.4.2  Cut and cover survey duration

The department will confirm the duration and number of dilapidation surveys required based on the pre-construction dilapidation survey report, a minimum of two dilapidation surveys will be requested. The first, is to be undertaken prior to any construction/demolition works (pre-construction) and the second at completion of the construction works (that is, post construction).
9.4.4.3 Dilapidation survey costs

The developer is responsible for the dilapidation survey costs. These costs vary depending on the features of the tunnel, development and the condition of the tunnel. Table 9.4.4.3 details some of the usual associated costs. This is not a complete list.

Table 9.4.4.3 – Potential tunnel dilapidation survey costs

<table>

| Road tunnel (Non Toll)       | Transport and Main Roads  | Negotiate with relevant management authorities       | Traffic control costs:  
Developer and Transport and Main Roads engineering dilapidation survey staff costs.  
Mobile elevated work platforms hire, other machinery and equipment hire and labour costs.  
Tunnel induction costs. |

Note 1 - Indicative only. Additional cost may be required.

9.4.5 Tunnel monitoring requirements

a) During the demolition / excavation / construction phases, the following issues are to be addressed by the developer:

• dilapidation, vibration, tunnel movements, crack growth and soil movement
• instability of the excavation wall adjacent to the tunnel
• ground water fluctuations behind the tunnel
• change in vertical stress at levels equal to the top and bottom of the tunnel, and
• effect of change in vertical stress on the horizontal stiffness of the rock adjacent to the tunnel and any significant risk implication for the long-term stability and structural safety of the tunnel structure.
b) A monitoring program shall be prepared by the developer in consultation with the department to ensure that the tolerances for vibration, crack, movements / deformation, ground tunnel tolerances are not exceeded. The preparation and running of the monitoring program will be at the expense of the developer.

c) Monitoring shall be conducted for two weeks prior to commencement of work to establish base level conditions, during construction, and for a minimum of three months after completion of work. Monitoring can be terminated only with the acceptance of the departmental Representative, upon demonstrating that the monitoring results confirm that the site conditions have stabilised.

d) These timeframes are a baseline indication of the department’s requirements. Monitoring plans and programs will need to be prepared for each development to respond to local conditions, tunnel type and the position of the development relative to the tunnel.

e) The monitoring requirements are governed by the position of the development relative to the tunnel. Two scenarios are considered:

- development adjacent to a tunnel, and
- development above a tunnel.

**Development adjacent to a tunnel**: occurs where NO part of the development excavation or building structure is located above the tunnel structure or tunnel volumetric boundary.

**Development above a tunnel**: occurs where ANY part of the development excavation or building structure is located above the tunnel structure or tunnel volumetric boundary.

### 9.4.5.1 Development adjacent to and above a tunnel

Monitoring requirements for developments adjacent to and above a tunnel is shown in Table 9.4.5.1.

**Table 9.4.5.1 – Monitoring requirements for developments adjacent to a tunnel**

<td>Yes</td>
</tr>
</tbody>
</table>

Note: 1 The department reserves the right to overwrite these requirements
In any instance where a development proposes intrusion into the tunnel volumetric boundary or is closer than the department’s permitted tolerances, tunnel monitoring requirements are to be assessed on a case by case basis.

9.4.6 Ground water monitoring

The Contractor’s work method and system shall be designed to control ground water. Removal of ground water shall not cause damage to the existing tunnel structure. In particular:

- Significant lowering of natural ground water table shall be avoided.
- The Contractor shall install minimum of two piezometric devices to determine the seasonal fluctuations in ground water between the tunnel and the new development.
- The developer’s engineer requires collection and review of all inclinometer and ground water monitoring data on a daily basis during the excavation stage of the basement earthworks, and thereafter weekly until three months after completion of the basement construction, unless more or less frequent monitoring is deemed acceptable by the department’s representative, and
- Unusual fluctuations are to be reported immediately to the department’s representative.

9.4.7 Tunnel movement monitoring

a) The developer shall install monitoring (24/7) system using automated total station to capture the movements in tunnel and associated structures including the developer’s retention system. This monitoring system shall provide an efficient means to evaluate the trend of movements in a structure. The total station instruments shall have angular, distance measurement and autolock accuracies. The total stations consist of robotic instruments that shall have the ability to search and lock onto series of sensors attached on the structure automatically.

b) The type of instruments, its location and its proximity to the targets shall be appropriate for the sensitivity required. At critical locations of the structure, in addition to total stations, structural sensors such as tilt meters shall be installed to capture precise movements. Structural sensors shall be installed at critical locations at the same time as prisms are installed for the total stations, prior to commencement of construction of the new development. This ensures enhanced accuracy is already in place and precise readings available to monitor critical locations should the trigger level is approaching unacceptable values.

c) The data captured by the automatic monitoring system shall be consistent and stable. The accuracy of the system shall be such that the deviation from the mean reading (which is taken as the actual reading) shall be less than ±2 mm for 99% confidence level.

d) The number of prism sensors and its locations are dependent on the type of structures to be measured and the outcome of the tunnel impact studies (refer Table 9.3.4) due to the adjacent development. It is prudent to install prism sensors at the locations where tunnel movement is predicted to be a maximum (by structural analysis) should movement occur during construction of the development. Alternatively the prism sensor locations can be identified from deformed shape outputs from Finite Element Studies.

e) The movement shall be measured in the tunnels or associated structures in the transverse, longitudinal and vertical directions. The allowable movement in any of these three direction shall not be greater than 5 mm.
f) The automated notification trigger for movements shall be set as follows:

Automated Notification Trigger = Allowable Movement + Instrument Uncertainty (± 2 mm at 99% confidence).

g) In the event that the total station readings indicate a trend in movement, additional prism sensors shall be placed at, and near the affected zone, or critical area identified and frequency of monitoring shall be increased. If the trend continues additional structural sensors shall also be installed.

h) During the progress of the development works, if it becomes apparent from the monitoring results that the ground/or the Developer’s retention system exceeds the predicted maximum movement, the Developer shall strengthen the retention system. Revised retention system shall be certified by the Developer’s RPEQ.

i) Trigger levels for tunnel movements and associated structures shall be agreed with the department prior to commencement of construction.

9.4.8 Vibration monitoring

9.4.8.1 General

a) The developer is required to install vibration monitoring equipment utilising triaxial geophones (4.5 Hz) to capture vibration in the tunnel roof and or walls prior to commencement of any demolition, excavation or construction work. The devices shall be calibrated against a traceable event. The devices shall be installed as per manufacturer’s installation guidelines. The output result shall also include waveforms of extreme events.

b) A suitable measurement frequency to be specified by the instrumentation designer, such that all events are captured, to avoid the two scenarios - low and high measurement frequencies. The first will lead to data overflow and the second will miss critical events.

c) Background monitoring and baseline reading shall determine and correct external influences on monitoring results (for example, temperature, traffic, atmospheric pressure) which can lead to errors in reported data. Hence a two month baseline reading regime is imposed.

d) System reliability is important as a lack of monitoring results may result in limitations on works or even suspension of construction operations. Where the consequences of monitoring system failure are unacceptable to a project, there shall be sufficient redundancy built into the system so that losses of discrete elements do not cause loss of the entire monitoring system.

e) Monitoring systems require routine checks and maintenance. Most monitoring systems require some access for maintenance. The monitoring designer must consider how this can be achieved. A log of maintenance undertaken on the system is recommended. This log shall record the date, nature of the work and who undertook it. This is useful for error tracing and a change in control procedures.

f) The location and number will be accepted on a project basis.

9.4.8.2 Trigger and alarm limits

9.4.8.2.1 Bored/Driven tunnels

a) A PCPV (Peak Component Particle Velocity) threshold of 1.5 mm/sec is to be set in the logger.
b) A warning trigger level between 1.5 mm/s to 5 mm/sec is to be set in the logger.

c) The trigger level to close the tunnel to buses or traffic and immediate ceasing of all excavation is to be set at a PCPV exceeding 5 mm/s.

d) Responses to trigger levels of bored/driven tunnel lining vibration monitoring shall comply with those listed in Table 9.4.8.2.1.

Table 9.4.8.2.1 – Vibration: alarm limits and responses for bored/driven tunnel

<table>
<thead>
<tr>
<th>Trigger Levels</th>

<td>Stop all buses or traffic from using tunnel. Place hold on excavation. Notify the Developer’s Supervising Engineer and Transport and Main Roads. Resumption of work to be approved by the department.</td>
</tr>
</tbody>
</table>

Any changes to the above trigger based on the background information or at any time during the adjacent development is to be accepted by the Transport and Main Roads, Director (Structures Review and Standards).

Typically “Vibration Geophone” accuracy is ± 0.1 mm/s

9.4.8.2.2 Cut and cover tunnels

The following trigger levels shown in Table 9.4.8.2.2 shall be set for cut and cover tunnels.

Table 9.4.8.2.2 – Vibration alarm limits and responses for cut and cover tunnels

</tbody>
</table>

9.4.8.3 Alert and response plan due to vibration and movements

The developer has to provide an “Alert and Response Plan”. The “Alert and Response Plan” provides the alarm and reporting procedure in the event of unprecedented settlements, ground movements,
tunnel liner rotation or vibrations of the tunnel during demolition and excavation for the basement and other construction works.

The “Alert and Response Plan” shall show the contact chain in case of alarm. Relevant departmental (TransLink Division and Engineering and Technology Branch) representatives shall be the first to be informed.

9.4.9 Crack monitoring device

9.4.9.1 General

The developer is required to install crack monitoring devices in the tunnel before the start of any demolition, excavation or construction. Suitable crack meters with accuracy and reliability are to record the crack growth inside the tunnel. The location and the number of devices to be installed for crack monitoring are to be selected after the cracks are identified from the dilapidation survey.

9.4.9.2 Trigger and alarm limits for crack

Responses to trigger levels of tunnel lining crack monitoring shall comply with those listed in Table 9.4.9.2.

Table 9.4.9.2 – Tunnel lining cracks, alarm limits and responses

<table>
<thead>
<tr>
<th>Trigger Levels</th>
<th>Tunnel Lining Crack Width (Crack Monitoring)</th>
<th>Responses</th>

</tr>
</tbody>
</table>

9.4.9.3 Alert and response plan due to cracking

The Alert and Response Plan shall show the contact chain in case of alarm. Relevant departmental (TransLink Division and Engineering and Technology Branch) representatives shall be the first to be informed.

9.4.10 Ground movement adjacent to the tunnel

The development proponent shall undertake the following monitoring of ground adjacent to the tunnel.

9.4.10.1 Inclinometer

a) Install at least three inclinometers at critical locations between the existing tunnel and the proposed basement to a depth well below the basement excavation level. The decision to increase / decrease the number of inclinometers based on the proximity of the excavation adjacent to the tunnel and the length of excavation is at the discretion of the department’s representatives.
b) The inclinometer must be monitored daily during basement excavation and weekly until three months after completion of basement construction. The developer’s consultant is required to collect and review all inclinometer data during the excavation stage as well as the basement construction stage. Reports are to be forwarded to the department for review.

c) Trigger and alarm limits for inclinometer movements are to be agreed prior to commencement of any demolition, excavation or construction work.

The Alert and Response Plan for inclinometer movement shall show the contact chain in case of alarm. The first stakeholders to inform are TransLink and Transport and Main Roads.

9.4.10.2 Instability of development excavation wall adjacent to state-controlled tunnel

a) Basement construction adjacent to state-controlled tunnels and retaining walls may include temporary and permanent retention systems by the development proponent. Survey monitoring points or inclinometers shall be placed on the development’s retention system including the capping beams. The load on struts and/or anchors also to be monitored.

b) The number of monitoring points required shall be proposed by the developer’s RPEQ, reviewed and agreed by the department to ensure sufficient measuring points capture any potential movement on the development’s retaining wall. Carry out monitoring twice a day during excavation and once a day when no excavation work is undertaking on site. Daily reports shall be forwarded to the department for review.

9.5 Additional requirements for tunnels

a) Excavation, installation of services or other construction works under the tunnel is not permitted without the written acceptance of Transport and Main Roads prior to commencement of works. The department will advise of the design checks required to be accepted, prior to commencing work, on a case-by-case basis.

b) Installation of permanent anchors within the tunnel volumetric boundary area for structures from adjacent properties is not permitted.

c) Acceptance to install temporary rock anchors that protrude into the tunnel volumetric area or within 2 m of the state-controlled tunnel infrastructure shall be obtained prior to undertaking the works.

d) Temporary retaining structures such as anchors / shoring may be potentially installed in state-controlled properties, subject to the development proponent adequately demonstrating through RPEQ certified assessment and drawings that the integrity and safety of the state-controlled transport tunnel will not be compromised. Temporary anchors shall be de-stressed prior to the completion of construction. Certification of the de-stressing by relevant experienced RPEQ shall be submitted to the department within 28 days of the de-stressing operation.

e) Post tensioned transfer slabs and beams constructed on top or adjacent to tunnels for the development shall be witnessed by departmental representatives during construction to confirm the design post tensioning force had been applied (Witness Point). The Developer shall submit RPEQ certified records of the measured post-tensioning forces and hogs to Transport and Main Roads Director (Structures Review and Standards) for review within 14 days of completing post-tensioning. Further construction works over the tunnels shall not
be carried out after completing post-tensioning without agreement with the post-tensioning records and hogs from Director (Structures Review and Standards).

f) Excavation close to tunnel (agreed and allowed by Transport and Main Roads) to be witnessed by the department. (Witness Point). Any back filling next to tunnel shall not be carried out (Hold Point), before inspection by the department.
10 Gantries and support structures

10.1 Applicability

These design criteria apply to all structures as given below:

- above road gantry structures
- above road cantilever structures
- tolling structures on carriageway and side of the road
- traffic light poles in excess of the parameters given in Transport and Main Roads Specifications MRTS92 Traffic Signal and Road Lighting Footings, MRTS94 Road Lighting and MRTS97 Mounting Structures for Roadside Equipment, and
- all sign supports on the side of the road for signs greater than 7.5 m wide or 8 m high or 40 m²

Note that supports for traffic signs and tolling systems on the side of the road up to 7.5 m wide or 8 m high up to a maximum area of 40 m² may be designed in accordance with the Transport and Main Roads Manual Design Guide for Roadside Signs.

Refer to Chapter 11 for Roadside advertising signs.

10.2 Provision of ITS devices and support structures

The requirements for selection of appropriate ITS devices and the support structures required to position them are given in different Transport and Main Roads manuals and Technical Specifications. The design, details and requirements for ITS devices are given in general and specific ITS Technical Specifications as shown in Table 10.2.

Table 10.2 – ITS Specifications

</tr>
</tbody>
</table>
In order to aid the selection process, refer to Technical Note 123 and the attached flow charts. These flow charts do not take precedence over the requirements in the documents.

### 10.3 Clearance

The minimum vertical clearance of the structure or sign face (whichever is lower) above the pavement shall be 6600 mm (6500 mm plus 100 mm for future overlays) after allowing for vertical deflection from permanent loads. When the structure is not over the road or road shoulder or parking or areas accessible by vehicles, minimum of 2400 mm vertical clearance above the ground level to the underside of the sign face or any structure component shall be maintained to prevent collision with pedestrians.

These design criteria override and take the precedence over other documents.

### 10.4 Additional design requirements

#### 10.4.1 Design life

The design life shall be:

- "above carriageway" structures or structures that could fall onto the road - 100 years
- other support structures on the side of the road - 50 years

#### 10.4.2 Live load

Sign structures that have a maintenance platform shall be designed for live loading of 5 kN concentrated moving load over 1 m² simultaneously with 2.5 kPa distributed load elsewhere. The platform shall also be designed for concentrated load of 1 kN over 300 mm square patch located anywhere on the platform floor.

#### 10.4.3 Aesthetics

Support structures shall be aesthetically compatible with other similar structures in the road network.

#### 10.4.4 Corrosion protection and durability

a) The minimum protection of all steel shall be hot-dip galvanising to AS/NZS 4680 including all internal surfaces of circular members.

b) If the steelwork is hot dipped galvanized then:

- Connections shall be sealed on all faces to stop the ingress of water and galvanising acids which causes corrosion at interfaces. Where access for welding is available to one side of a joint only, a full penetration butt weld shall be used.
- Where backing bars / backing rings are used inside members, the backing bars / backing rings shall be removed prior to galvanising. If they are not removed, acid is trapped between the backing bars / rings and the member resulting in crevice corrosion.
- The size of the components shall be checked to ensure that they can be hot-dipped galvanised after fabrication. Double dipping shall be allowed.

#### 10.4.5 Concrete durability

The minimum exposure classification for the purpose of determining cover to reinforcement and the concrete mix for structures of design life 100 years shall be B2 to AS 5100. The exposure classification for structures of design life 50 years or less shall be minimum A2 to AS 3600.
Also refer to Section 3.8.4 for additional requirements of concrete durability.

### 10.4.6 Serviceability deflection

The self-weight, live loads and serviceability wind loads shall be taken into account for deflection calculations. The deflection criteria for structures with electrical and electronic equipment shall be specified separately. For example structures that support cameras or Free Flow Tolling devices shall be designed for deflection limits stipulated by the camera or device designer. The deflection calculations for all structures shall include the long term creep deflection resulting from the foundation movement. Deflection criteria for portal and cantilever structures are provided in Tables 10.4.6(a) and 10.4.6(b).

**Table 10.4.6(a) – Deflection criteria for portal structures**

</tr>
</tbody>
</table>

Note 1: Maximum span for cantilevered gantries shall not be greater than 9.5 m, from centreline of the column to the end of the horizontal arm.
10.4.7 Vibration

Vibration limits shall be in accordance with AS 5100 and the manufacturer’s requirements for each particular ITS device.

10.4.8 Foundations design

a) Geotechnical requirements in foundation design including design methodology, geotechnical investigations, design documentations and so on, shall be in accordance with Transport and Main Roads Geotechnical Design Standard - Minimum Requirements. In addition to that, requirements stated in this document shall also be met.

b) Foundation design for structures shall be based on specific foundation investigation at the sign location to a minimum depth of one full height of the structure unless otherwise directed by RPEQ (Geotechnical) Engineer. Experienced RPEQ Geotechnical Engineer who is Transport and Main Roads pre-qualified, shall certify the geotechnical report which shall also include advice to ensure that long term foundation rotation does not result in column deflection in excess of the serviceability deflection limits stated in Clause 10.5.6.

c) The geotechnical investigation shall identify potential Acid Sulphate Soils. The Designer shall use MRTS51 Environmental Management and MRTS04 General Earthworks to specify the treatment of acid sulphate soils if this is present on the site.
d) Gantry and support structure foundations such as pile caps, footings etc., shall be installed below ground level with the top surface of the pile cap or footing at the same level as the surrounding ground surface level with appropriate falls and detailing to ensure surface drainage falls away from structural baseplates. Column baseplates shall be installed above ground on a bearing plinth with suitable provision for drainage. Column base plates shall be accessible for inspection and it shall be closer to ground level.

10.4.8.1 Foundation types acceptable for gantries and support structures

a) Cast-In-Place piles to MRTS63 Cast-In-Place Piles or MRTS63A Piles for Ancillary Structures as applicable.

MRTS63A Piles for Ancillary Structures is applicable for piles for high moment low axial load applications such as single cast-in-place piles. Piles in a pile group where axial load is dominant due to the moment couple shall be in accordance with MRTS63 Cast-In-Place Piles.

b) Prestressed concrete driven piles to MRTS65 Precast Prestressed Concrete Piles.

c) Spread footings.

Any other foundation types shall be agreed with Transport and Main Roads (Structures) prior to start of design.

10.4.8.2 Foundation types not permitted for gantries and support structures

a) The following foundation types are not accepted for use in foundations with a 100 year design life, to structures “above carriageway” or those located above a railway:

- steel screw piles
- Continuous Flight Auger (CFA) piles
- precast reinforced concrete piles
- steel piles (except for Western Queensland, refer Section 4.1.6)
- precast concrete piles manufactured by spinning or rolling
- piles constructed with bentonite or polymer slurry, and
- bored piles without permanent steel or concrete liners.

b) Any Proponent, who believes the use of such piles is cost effective and will achieve the strength and durability required, may prepare a written submission for assessment by the department’s Director (Structures Review and Standards). Delays in assessing such submissions, and any consequent costs are entirely the responsibility of the Proponent. The department’s publication Engineering Innovation outlines the steps involved in the innovation process, which takes time and should ideally be done outside of a Contractual situation, at the concept design stage.

c) The foundations shall be designed so that the base plate is installed as close to ground level as possible while providing for drainage and other requirements. The design length of the support columns shall take into consideration the variations in the reduced levels of the foundations.
10.5 **Structural design**

10.5.1 **Wind loading**

Wind load shall be calculated in accordance with AS 1170.2 with wind perpendicular and at 45 degrees to the sign face. Drag force coefficient $C_d$ shall be in accordance with AS/NZS 1170.2.

a) **Ultimate strength**

   Ultimate strength structural design shall be to AS 5100.

   ARI for ultimate limit state wind speed shall be 2000 years.

b) **Serviceability**

   ARI for serviceability limit state wind speed shall be 20 years.

10.5.2 **Structural design criteria fatigue**

10.5.3 **Load combinations**

Load factors and load combinations shall be to AS 5100.

10.5.4 **Signs attached to bridges – additional design criteria**

The following criteria apply to the structural design and fabrication of sign structures mounted on Transport and Main Roads bridges. Other regulatory requirements and standards that must be complied with are outside the scope of these design criteria.

10.5.4.1 **Type 1 - Signs attached to reinforced concrete traffic barriers on bridges**

The sign structure shall be designed to remain intact when the barrier is impacted by traffic to prevent the structure from falling onto pedestrians and traffic below. The structure shall be attached to the outside face of the reinforced concrete barrier.

10.5.4.2 **Type 2 - Signs attached to bridges with steel traffic barriers**

The sign structure shall be supported independent of the steel traffic barrier, and positioned beyond the deflection limits of the traffic barrier. The sign structure shall not be impacted when the traffic barrier is impacted by a vehicle. For guidance of regular level steel traffic barrier detailed in Standard Drawing 2200 will deflect 100 mm when impacted.

10.5.4.3 **Common to both Types 1 and 2**

a) The structure supporting the sign shall be positioned outside the “working width” so that if the barrier is impacted by a vehicle, the vehicle will not impact the sign structure.

c) For large signs requiring a Level 2 structural inspection the sign structure shall have a horizontal clearance of 50 mm minimum from the near face of the bridge traffic barrier. The horizontal gap between the face of the traffic barrier and the rear of the sign shall be sealed with a galvanised perforated steel sheet (maximum 10 mm diameter holes) along the full
length of the sign structure. This is to prevent vandals hidden behind the sign and dropping objects onto the motorway below. This is a “Safety In Design” requirement.

d) The design shall prevent access by vandals to the sign structure and tamper proof fastenings and connections shall be used.

e) The sign structure shall not restrict access for maintenance and repairs to the traffic barrier. Drilling or coring into prestressed concrete is NOT permitted. Signs shall be attached with stainless steel or hot dip galvanized bolts.

f) When a sign structure is attached to a bridge over road, the design live load for assessing the bridge structure shall be the original design loads used in the design of the bridge.

g) The impact load on the barrier shall be assessed using the Road Barrier Performance Level Selection Method in AS 5100. The result from this shall be used to determine whether it is justified to use the barrier impact load that the structure was originally designed for. Also refer to Chapter 7 Matters for Resolution in AS 5100, Item 19 for the procedure and requirements to determine the barrier performance level.

For comparison, the barrier impact load in the Bridge Design codes is as follows:

- NAASRA 1976  - 45 kN (working transverse outward load)
- Austroads 1992  - 90 kN (ultimate transverse outward load) for h < 850 mm
- AS 5100.2  - Low performance 125 kN (ultimate transverse outward load)  
  - Regular performance 250 kN (ultimate transverse outward load).

h) For bridges designed in accordance with the NAASRA or Austroads Codes, the minimum barrier impact load to be used for assessing the bridge structure in combination with the load effects of the advertising sign attached to the bridge, shall be 60% of low performance, that is 62 kN minimum impact load.

i) For bridges designed in accordance with AS 5100, the full impact load stipulated by AS 5100 for appropriate barrier performance level shall be used for assessing the bridge structure in combination with the load effects of the sign structure attached to the bridge. Designer shall determine the appropriate barrier performance level in accordance with the AS 5100.1 Appendix B.

j) Bridges designed prior to 1976 are considered as special cases and the appropriate barrier impact load shall be discussed with Transport and Main Roads Director (Structures Review and Standards).

k) The sign structure Designer shall check the structural adequacy of the bridge structure. The following additional load combinations for ultimate design shall be considered:

- Combination 1: Ultimate 2000 years ARI wind on sign plus ultimate dead load (bridge and sign structure), no traffic load on the bridge, no vehicle impact on the barrier.
- Combination 2: 10 years ARI serviceability wind on the sign plus ultimate dead load (bridge and sign structure) plus ultimate vehicle impact load on the barrier, no traffic load on the bridge.
Chapter 10: Gantries and support structures

- Combination 3: 20 years ARI serviceability wind on sign plus ultimate dead loads (bridge and sign structure), plus ultimate traffic loads on the bridge, plus serviceability live load on the sign structure working platform, no Vehicle impact on barrier.

10.6 Design of elements for structures

10.6.1 Maintenance platform

The department has published Standard Drawings 1573, 1577 and 1581 for new gantry structures. Additional guidance in this section has been developed in consultation with the department's WHS Advisor, for general requirements and for retro-fitting existing VMS structures that do not comply with AS 1657. Fall arrester systems have been standardised for consistency of equipment requirements across the department and to minimise variations as required by RoadTek.

a) Unless specifically nominated otherwise by Transport and Main Roads, all gantries and other structures supporting electrical and electronic equipment shall be provided with an access platform to allow maintenance of these equipment and structural components without disrupting traffic.

b) Where a maintenance platform is required, the maintenance platform shall comply with AS 1657 and additional criteria stated in this document. It shall be provided for the full length of the overhead structure. The platform design shall ensure that rear access doors to ITS devices are not obstructed by the platform.

c) The minimum width of the maintenance platform shall be 800 mm. However, the width shall be greater if required to conform to functional requirements (for example open doors, swing/sliding signs, and so on). Where cameras are mounted in the walkway, 800 mm walkway must be provided on one side of the camera and 500 mm maintenance access on the other side of the camera.

d) The platform shall be designed for live load stated in Clause 10.4.2. The serviceability deflection under any live load shall not exceed the limits stated in Clause 10.4.6.

e) All walkways and platforms shall have permanent plates secured and displayed in a prominent position stating the maximum design loads for the walkways and platforms and any constraints to loading intensity. These plates shall be detailed on the drawings conforming to the appropriate Australian Standards.

f) Floor of the maintenance platform shall be a grated floor to comply with AS 1657 Clause 3.2.3 Flooring materials and 4.3 Platform Surfaces. The floor shall have a non-slip finish and be self-draining. The “Weldlok” A40-205 floor grating is acceptable to Transport and Main Roads. A protection mesh shall be fitted on to the top of the grated floor to protect objects, maintenance tools and equipment from falling onto the area below. Gaps larger than 10 mm at the ends of the floor which permit items to fall on to the area below shall be fitted with the mesh. The protection mesh shall be an expanded metal with the minor axis not exceeding 10 mm and minimum thickness of 1.6 mm. “Mastermesh Industries” LD1616 mesh is acceptable to Transport and Main Roads.

g) The platform shall be free of sharp corners and projections that can cause injury.
Chapter 10: Gantries and support structures

h) Guardrailing shall be provided on the maintenance platform. Guardrailing shall comply with AS 1657 Clause 5.4 Guardrailing and have:

- top of the top rail at 1100 mm height from the floor.

- One or more middle rails having a maximum clear distance of 450 mm between the rails and a maximum clear distance of 450 mm between the lowest rail and the top of the toe board.

- a toe-board which shall not be less than 100 mm above the top of the floor. Toe-board shall be provided all around the floor of the platform except at the platform entrance. Toe-board shall be made using structural steel angle of minimum 3 mm thick.

- a protection mesh made from expanded metal mesh with the minor axis not exceeding 10 mm and minimum thickness of 1.6 mm to infill between all the rails and top of the toe-board to ensure that objects, maintenance tools or equipment cannot fall on to the area below. “Mastermesh Industries” LD1616 mesh is acceptable to Transport and Main Roads. The mesh panelling shall be designed to ensure that it will not interfere with ITS equipment operation.

- no gaps greater than 50 mm (with or without a mesh) between ends of the guard railing and the structure.

i) Any vertical gaps between the floor of the maintenance platform and the rear of the ITS device shall also be fitted with mesh similar to the mesh fitted with the guardrails to prevent objects, maintenance tools and equipment from falling to the roadway.

j) Unless otherwise specified, access to the maintenance platform shall be by fixed ladder systems from ground level designed and installed to:

- AS 1657 Fixed platforms, walkways, stairways and ladders – Design, construction and installation

- AS/NZS 1891 Industrial Fall-arrest systems and devices – harnesses and ancillary equipment

- Safe Work Australia Code of Practice

- WHS legislations, and

- additional criteria stated in this document.

10.6.2 Access ladder and landings

a) The ladder system and the landing shall be designed and installed in accordance with AS 1657. The access structure shall be considered as a workplace, and the access provisions must conform to the appropriate act and regulations. The access shall be secured and ensure unauthorised persons cannot enter the structure.

b) For new structures, the requirement of intermediate landing and ladder cage shall be in accordance with Table 10.6.2(a) and AS 1657.
Table 10.6.2(a) – Details of the fall protections

<table>
<thead>
<tr>
<th>Structure type</th>
<th>Fall distance</th>
<th>Fall protection provisions</th>
<th>AS 1657 reference clauses</th>
</tr>
</thead>
</table>
| Ladder is within four post gantry column | Up to 6.0 m | - Ladder cage  
- For existing structures, if ladder cage is not possible, a harness based fall-arrest system to AS/NZS 1891 (series) shall be provided. | Clause 7.4.7: Note 2 |
| | > 6.0 m | - Ladder cage, and  
- Intermediate landing at maximum of 4.5 m height. Vertical height between landings in multiple flight ladders should be equal.  
- For existing structures, if ladder cage is not possible, a harness based fall-arrest system to AS/NZS 1891 series shall be provided. | Clause 7.3.6, 7.4.7 and Table G1 (rung type ladder – twin stiles)  
Clause 7.3.6: Note 2 |
| Ladder is fixed other than four post gantry columns, e.g. single post VMS structure | Up to 6.0 m | - Ladder cage  
- For existing structures, if ladder cage is not possible, a harness based fall-arrest system to AS/NZS 1891 (series) shall be provided. | Clause 7.4.7 |
| | > 6.0 m | - Ladder cage, and  
- Intermediate landing at maximum of 4.5 m height. Vertical height between landings in multiple flight ladders should be equal.  
Omit intermediate landing where installation of intermediate landing is “not reasonably practicable” (Example: A single post VMS structure where an intermediate landing will fall within the working width or over the carriageway). A harness based fall-arrest system to AS/NZS 1891 series shall be provided. | Clause 7.3.6: Note 3 |

c) When intermediate landing with multiple ladders are used, the ladder arrangement shall be in accordance with AS 1657.

d) Fall arrester harness systems shall comply with AS/NZS 1891. The harness system shall be capable of arresting falls within a short drop of not greater than 600 mm. The Designer shall be responsible for nominating the type of harness and providing attachment points in the structure. The approved fall arrester system shall have Certification and Approval to AS/NZS 1891 (Series): Industrial fall – arrest systems and devices – harnesses and ancillary equipment.

Table 10.6.2(b) and Figure 10.6.2 show the details of the fall arrester system manufactured by SafetyLink Pty Ltd which is acceptable to Transport and Main Roads.
Table 10.6.2(b) – Details of the fall arrester system

Following additional requirements shall also be met:

1. At the bottom of the ladder, the following sign and the wording shall be attached.

2. The base of the ladder shall be kept above the base slab for improved durability. The height to the first rung from base slab shall be not greater than the standard rise. All rises shall be equal except that the first rise may be less than the standard height.
3. Screens shall be provided around the outside of the ladder to prevent children and unauthorised persons from accessing the ladder from the gap between the column and the back of the ladder.

4. All other requirements of AS 1657 shall be strictly adhered to, and are not open to interpretation.

5. VMS gantries have adjustment rods on the signs. These rods protrude horizontally and shall be capped with a suitable cap to prevent injury.

6. Following erection a competent person (as defined in the Work Health and Safety Act 2011) shall be engaged by the gantry supplier to carry out an inspection and comprehensive safety audit of the gantry for compliance with AS 1657 and WHS legislations prior to handover to Transport and Main Roads.

8. The gantry supplier shall provide a metal Compliance Plate with the Registration Number embossed on it and securely attach the Compliance Plate to the structure with vandal proof fastenings

10.6.3 Access to the structure site

a) The design must incorporate a path from where maintenance staff can park a vehicle and gain access to the structure. Access to the structure site shall be designed to ensure that maintenance personnel can access the structure safely. Routine operation and maintenance access to the structure shall not require traffic control measures, and/or lane closures.

b) Provision shall be made for impact protection of maintenance personnel from errant vehicles.

10.6.4 Wiring enclosures

a) All wiring enclosures for installation of power cables must comply with AS/NZS 3000 and the relevant Transport and Main Roads Technical Specifications.

b) All wiring enclosures for telecommunications cables must comply with AS/ACIF S009 and the relevant Transport and Main Roads Technical Specifications.

c) Conduits must comply with Transport and Main Roads Technical Specification MRTS91 Conduits and Pits.

10.6.5 Bolts, nuts and washers

a) Steel bolts, nuts and washers shall be in accordance with MRTS78 Fabrication of Structural Steelwork.

b) Self-tapping screws are not permitted to use in structural connections and to connect sign face to the structure. Bolted connections with two nuts in predrilled hot dipped galvanised holes shall be used to connect structural members.

c) Self-tapping screws are permitted to fasten cladding only.
10.6.6 Anchor bolt/rod details

On the basis of NCHRP reports and learnings from interstate sign failures, the following must be observed:

a) Connections using Class 4.6 bolts are less likely to be controlled by fatigue requirements than are those which use Class 8.8, however either grade may be used provided that the design satisfies both ultimate strength and fatigue life requirements. Class 8.8 bolts shall conform to Transport and Main Roads Technical Specification MRTS78 Fabrication of Structural Steelwork.

b) Pre-tensioned bolts are not warranted.

c) Nut tightening and the use of lock nuts are important to prevent nut loosening, which in turn will cause undesirable larger stress fluctuations, thus increasing the risk of fatigue failure.

d) Snug tightening is adequate for fatigue performance provided it is done properly and provided lock nuts are:
   • purpose made half height nuts
   • made from softer steel than the ordinary nut, and
   • are located between the ordinary nut and the base plate.

e) For Class 8.8 bolts ONLY, to more reliably prevent loosening, tightening in the range 1/2 turn to 1/3 turn beyond snug tight, depending on bolt class and diameter, is now preferred (in conjunction with lock nuts).

f) The maximum unsupported length of the anchor from top of footing to the bottom of the base plate to be not more than one anchor diameter.

10.6.7 Base plate thickness

The base plate shall be at least as thick as the anchor diameter.

10.6.8 Structural steel

Structural steel material shall meet the requirements of Section 4.16

10.6.9 Provision for drawing cables and wiring

a) The design of the structure shall provide adequate radii for redirecting cables and wiring around bends, appropriate for the diameter and type of cable in accordance with the relevant Australian Standards.

b) The drawings shall note that all access holes for cables and wires shall be fabricated without sharp edges to prevent damage to insulation when the cables are drawn.

c) The Drawings shall note that no additional holes are permitted to be drilled that are not shown on the RPEQ Certified drawings without approval from the Structural Designer and the Administrator.

10.7 Drawings and design report

a) The design submission shall include the Design Report and the drawings for construction. Drawings shall comply with the Transport and Main Roads Drafting and Design Presentation Standard Manual, Volume 3, Structural Drafting Standard. All engineering drawings shall be
certified by an appropriately experienced RPEQ Engineer. The RPEQ Engineer shall also certify on the drawings that the design complies with the relevant Australian Standards relating to Workplace Health and Safety.

b) The Design Report shall provide an installation procedure for the structure.

c) Drawings are to incorporate the following:

- Foundation layout, position, reduce levels shall be shown on the drawings.
- All design loads for the structure are to be shown on the structure specific drawings and walkways and platforms shall have permanent plates secured and displayed in a prominent position stating the design loads for the walkways and platforms. These plates shall be detailed on the drawings.
- The erection sequence shall include all requirements for tightening of hold-down bolts prior to grouting and prior to attachment of outreach arms.
- Construction drawings should include a diagram showing column offset and outreach pre-camber. Designers should calculate column offset based on provision of a 1 in 40 slope after allowance for long-term progressive foundation movement.
- Use of upper and lower templates for hold down bolts is recommended to ensure a good fit with holes in the base plate. Bending of hold down bolts and use of enlarged bolt holes are not permitted without written permission of the Designer.
- Impact protection from errant vehicles.
- Drainage water should be directed away from the footings of cantilever sign structures to prevent softening of the surrounds and corrosion of base plate and holding down bolts. Concrete paving with or without drainage channels may be appropriate in some areas, and
- All welds are to be detailed on the drawings and weld symbols shall be in accordance with AS 1101.

d) Notes for the construction of structures shall be shown on the set of drawings for the structure. Notes shall be consistent with the standard Transport and Main Roads notes in *Drafting and Design Presentation Standard Manual, Volume 3, Structural Drafting Standard* and shall address the following additional issues:

- prior to concreting, excavated foundations shall be inspected by the Geotechnical Assessor, and
- only those welds shown on the drawings are permitted. No weld is to be omitted or added without the specific approval of the Administrator.

### 10.8 Transport and Main Roads review of drawings and design report

a) Designs shall be submitted at preliminary design (15%), 50% substantial completion (unchecked drawings), 85% complete (checked drawings) and 100% complete for final acceptance prior to fabrication. The submission shall include drawings, geotechnical report and design report. The Design Report shall include discussion of safety, durability, future performance, constructability and maintenance and shall include a summary of deflections. The preliminary design submission shall involve a meeting between Transport and Main
Roads (Structures) and the Designer to discuss the drawings. The design shall not proceed until all issues are resolved.

b) For each submission, Transport and Main Roads will provide comments that the Designer must consider and these shall be included in the design. If the comment is not acceptable to the Designer, reasons shall be discussed with the Director (Structures Review and Standards). A final position acceptable to Deputy Chief Engineer (Structures) shall be reached. This solution shall be adopted.

c) Fabrication shall not begin until final drawings have been submitted to the Department and accepted by the Department. Fabrication shall not begin until all hold points and witness points in MRTS78 Fabrication of Structural Steelwork are released by Transport and Main Roads.

10.9 Fabrication of structural steelworks and aluminium components

a) Fabrication of the structural steelwork shall be to MRTS78 Fabrication of Structural Steelwork. Fabrication of aluminium components shall be to MRTS79 Fabrication of Aluminium Components.

b) All hollow sections shall be joined using full penetration butt welds. Fillet welds are not acceptable for this application as they encourage crevice corrosion resulting in premature failure.

c) All structural steelwork and all aluminium work shall be inspected by an appropriately experienced RPEQ Engineer or their approved delegate who is experienced in the fabrication of structural steelwork who shall ensure all the requirements of the specification are met.

d) The inspections shall be carried out during the fabrication process. The following documentation shall be supplied to Transport and Main Roads with the sign structure:

- Inspection Report outlining the welding procedures provided used the welds specified on the approved RPEQ Engineering drawings.
- Inspection Report outlining the review of the material test certificates to show compliance with the appropriate Australian Standards specified on the RPEQ certified Engineering drawings. The report shall state the member size and grade used in the structure. The report shall also outline the heat number and material test certificate number for the material supplied.
- Inspection Report outlining which butt weld preparations were inspected. This report shall include photos of each type of butt weld inspected with a bevel gauge showing the joint matches the approved welding procedure sheet.
- Inspection Report outlining the completed welds which have been inspected. The report shall show the welds inspected with the appropriate weld fillet gauge to show the conforming welds and the report shall show any welding defects identified in the inspection, and
- Inspection Report outlining the non-destructive testing carried out in accordance with the specification.

10.10 Installation of structure

a) Installation shall be in accordance with Transport and Main Roads Technical Specifications.
b) Transport and Main Roads does not permit the use of levelling nuts to support the structure. The structure shall be supported by proprietary non-shrink mortar with uniform distribution of the load over the whole plan area of the base plate. An acceptable procedure is as follows:

- stand the column section and level the column by placing a minimum of four steel wedges under each base plate
- mix the non-shrink mortar to a trowelable consistency
- pack the mortar and ensure that the mortar extends over the full area of the base plate
- wait for the mortar to set sufficiently to support the weight of the structure
- remove the steel wedges
- tension the bolts, and
- repair the mortar where the wedges were located.

c) All materials and bolts shall conform to the requirements of Transport and Main Roads Technical Specification MRTS78 Fabrication of Structural Steelwork.

10.11 Inspection

Large Traffic Management Signs (LTMS) that could fall onto the traffic lanes in the event of a structural failure such as gantries with signs over traffic lanes, cantilevers and butterflies (cruciform) as well as tall light masts and large signs with truss supports in close proximity to the traffic lanes are to be recorded in the inventory of the Bridge Information System (BIS) and will be subject to the inspection regime defined in BAM Support Advice Note No. 112: Large Traffic Management Signs-Inventory Creation & Inspection. The inspection category and inspection frequency to be as specified in LTMS Advice Note.

10.12 Protection of sign structures from vehicle impact

Portal frame and cantilever style overhead gantry supports within the clear zone as per RPDM (2nd edition) shall be protected by a traffic barrier from vehicle impact. The traffic barrier shall also be designed to suit road environment, traffic volume and mix, and road design speed.

10.12.1 Barrier deflection restrictions

The minimum nearside and offside distance to the edge of the lane and the barrier shall comply with AS 3845 Road safety barrier systems and devices - Road safety barrier systems and Transport and Main Roads Road Planning and Design Manual 2nd Edition, Volume 3. The barrier shall have sufficient clearance to the gantry to allow for barrier deflection and provide access for maintenance. It should be noted that all road safety barriers have a range of deflection values.

10.12.2 Working width restrictions

The sign support structure shall be located outside of the deflection zone of any road safety barrier and at a distance greater than the working width requirements behind the road safety barrier.

The working width takes into account the extent of body roll of a high vehicle striking the barrier. Refer to Figure 10.12.2 below, also the Transport and Main Roads Road Planning and Design Manual 2nd Edition, Volume 3. This ensures that the gantry is not subjected to vehicle impact loads that cause its collapse.
Chapter 10: Gantries and support structures

Figure 10.12.2 – Working width

10.12.3 Special design requirements

Special design requirements apply where the gantry support is incorporated:

a) within the road safety barrier itself, and

b) within the working width as described above.

For example, “butterfly” cantilever gantry designs that are installed within median barriers. Refer to the Figure 10.12.3 and the design methodology contained within this document.

Figure 10.12.3 – Gantry supports designs incorporated within road safety barriers” and within the working width

Notwithstanding the road safety barrier requirements below, it should be noted that “truss-design” supports, which are inherently more vulnerable, must not be incorporated within a road safety barrier design and instead must be protected behind a road safety barrier.

10.12.4 Traffic barrier design criteria

There are two design criteria, namely:

1. Normal road safety barrier where the gantry support is outside the working width.

2. Special road safety barrier where the gantry support is inside the working width.
10.12.4.1 Normal road safety barrier requirements where the gantry is outside the working width

The following conditions apply when the sign support structure is not incorporated within a road safety barrier:

a) Where cantilever or gantry mounted signs are to be installed that project across traffic lanes, the following is required to protect / shield the sign support structure:

- Where the posted speed of the road is 80 km/h or greater, a concrete road safety barrier is required. (The test level requirement will be dependent on the type of vehicle that is to be contained.)
- Where the gantry support is located in the area where two roads merge / diverge, that is the “gore” area, a crash cushion may be an acceptable solution used either on its own or in combination with a barrier as is required for the road environment.
- Where the posted speed of the road is less than 80 km/h, the minimum standard of barrier may be reduced to a steel or wire-rope road safety barrier.
- In an urban environment, where the posted speed of the road is less than 80 km/h, and the sign is located within the clear-zone, a road safety barrier may be required. Transport and Main Roads Road Planning and Design Manual 2nd Edition, Volume 3 for guidance on analysis and risk assessment of road safety barriers.
- In an urban environment, where the gantry is located outside the clear-zone.
- Where a kerb is present, a road safety barrier is not mandated, and
- Where there is no kerb, a road safety barrier should be considered based on a risk assessment as set out in the Transport and Main Roads Road Planning and Design Manual 2nd Edition, Volume 3.

b) Road safety barrier design.

Once the type of barrier required is determined, the barrier design including the "length of need" of the barrier is to be designed in accordance with the Transport and Main Roads Road Planning and Design Manual 2nd Edition, Volume 3. It is noted that there may be a section of road safety barrier where a higher performance is required; both on the approach and at the site of the gantry and this will need to be transitioned into any existing barrier.

c) On divided roads in urban environments where there are property accesses that prevent the installation of road safety barrier, the placement of the gantry support may be preferable within the median.

10.12.4.2 Special road safety barrier where the gantry support is in the working width

a) Where a “special” road safety barrier design is required, the design is considered to be outside the scope of standard Transport and Main Roads road safety barrier designs and the Road Planning and Design Manual, 2nd Edition. In such instances, the road safety barriers shall be designed in accordance with the “Special Performance” criteria outlined in AS 5100.1 – Table 10.4 and Clause 10.5.6 where the design speed of the road is 80 km/h or greater.
b) The road safety barrier shall be a rigid reinforced concrete barrier designed to resist the impact load and prevent barrier deflection, for example, by being supported on piles. The minimum effective height for the road safety barrier is 1600 mm above the pavement surface. (Refer to AS 5100.2 – Table A3). The minimum width of the road safety barrier shall be sufficient to protect the column during an impact, taking into account the working width.

c) With reference to AS 5100.2 – Table A2, “Special performance level barriers”, the ultimate transverse outward load is 750 kN (for a straight horizontal alignment, design speed 110 km/h), and 1000 kN (for a curved horizontal alignment, design speed 110 km/h). Thus, the minimum additional load on the steel column is 25% of 750 kN for a straight alignment, and 25% of 1000 kN for a curved alignment, applied one metre above the top of the road safety barrier. (This is a departmental requirement for robustness).

d) The minimum length of the section of “Special design” barrier is six metres each side of the gantry support structure. The minimum total length of the road safety barrier shall conform to the requirements set out in Transport and Main Roads, Road Planning and Design Manual 2nd Edition, Volume 3.

e) Timing for construction of the barriers.

The road safety barriers shall be constructed concurrently with the gantry support structures so that once they are erected, the permanent road safety barriers are in place to protect the gantry support structure from vehicle impact.
11 Roadside advertising signs

11.1 Applicability

a) These design criteria apply to the structural matters of design and construction of Roadside Advertising Sign structures. Other considerations such as “device distraction” and so on, shall be as referred to in other Transport and Main Roads regulations and standards. The relevant Transport and Main Roads Technical Specifications are available from the department’s website.

b) “Structural members” are members whose primary function is to provide a load path within the structure to support vertical, horizontal and torsional loads. These members collectively constitute the structure.

c) Following items are out of scope of this design criterion:
   - “Non-structural members” are members that do not contribute to the structural integrity of the structure. Typically, these are members that support the electronic devices and components, flashings for the “sign box” cladding and waterproofing and so on.
   - Advertising sign face.

d) Prior to the start of structural design, the Sign Licensee and Transport and Main Roads (Structures) shall agree on which members are to be designed as “Structural members” and “Non-structural members”.

e) This design criterion applies to all roadside advertising sign structures for two categories:
   - On-carriageway advertising signs.
     - Any sign structure that can fall and land on traffic lanes or on shoulders shall be considered as on-carriageway advertising sign. Following structure locations are classified as on-carriageway. Refer to Section 11.4 for design criteria for on-carriageway advertising sign structures.
     - The sign post is within the width of the carriageway plus shoulders, or
     - The sign post is located outside the area stated in - but the sign face is over the carriageway or shoulders as shown in the Figure 11.1(a).
     - The sign is attached to an overpass bridge.
   - Off-carriageway advertising signs
     - All structure locations that are not listed in item above shall be considered as off-carriageway advertising signs. A typical off-carriageway sign is shown in Figure 11.1(b). Refer to Section 11.5 for design criteria for off-carriageway advertising sign structures.
11.2 Sign licensee
Sign Licensee is a company who is the owner of the sign structure including the sign face, Sign Licensee company shall maintain a quality management system audited by a third party organisation and continually improve its effectiveness in accordance with AS/NZS ISO 9001 or ISO 3834.

11.3 Administrator
a) The Sign Licensee shall nominate the Administrator. Administrator shall be a registered Professional Engineer Queensland (RPEQ). All cost for this Administrator’s services shall be borne by the Sign Licensee.

b) The role of the Administrator is to:
   • ensure that all the appropriate permits have been obtained, and
   • release Hold Points and Witness Points in the relevant Transport and Main Roads Specifications and this document by RPEQ certification.

11.4 Design criteria for on-carriageway advertising signs
These criteria shall be applied for advertising sign locations stated in Section 11.1. Refer to Section 11.5 for design criteria for off-carriageway advertising sign structures.

11.4.1 Vertical clearance
a) The minimum vertical clearance of the structure or sign face (whichever is lower) above the roadway (carriageway plus shoulders) shall be 6600 mm (6500 mm plus 100 mm for future overlays) after allowing for vertical deflection due to permanent loads. When the sign face is not over the roadway or road shoulder or parking or areas accessible by vehicles, minimum of 2400 mm vertical clearance above the ground level to the underside of the sign face or any structure component shall be maintained to prevent collision with pedestrians.

b) When the sign structure is attached to an existing overpass bridge, vertical clearance to any component of the sign structure shall not be less than the vertical clearance of the existing bridge plus 50 mm.
11.4.2 Advertising signs attached to bridges

11.4.2.1 Geometric layout

The following criteria apply to the structural design and fabrication of advertising signs mounted on Transport and Main Roads bridges. Other regulatory requirements and standards that must be complied with are outside the scope of these design criteria.

11.4.2.1.1 Type 1 – Advertising signs attached to reinforced concrete traffic barriers on bridges

The sign structure shall be designed to remain intact when the barrier is impacted by traffic to prevent the structure from falling onto pedestrians and traffic below. The structure shall be attached to the outside face of the reinforced concrete barrier.

11.4.2.1.2 Type 2 – Advertising signs attached to bridges with steel traffic barriers

The sign structure shall be supported independent of the steel traffic barrier and positioned beyond the deflection limits of the traffic barrier. The sign structure shall not be impacted when the traffic barrier is impacted by a vehicle. For guidance a regular performance level double steel traffic barrier detailed in Standard Drawing 2200 will deflect 100 mm approximately when impacted.

11.4.2.1.3 Common to both Types 1 and 2

a) The structure supporting the advertising sign shall be positioned outside the “working width” so that if the barrier is impacted by a vehicle, the vehicle will not impact the sign structure. The “working width” is defined in Transport and Main Roads Road Planning and Design Manual 2nd Edition, Volume 3. These signs require Transport and Main Roads Level 2 structural inspections.

b) The sign structure shall have a horizontal clearance of 50 mm minimum from the near face of the bridge traffic barrier. The horizontal gap between the face of the traffic barrier and the rear of the sign box shall be sealed with a galvanised perforated steel sheet (maximum 10 mm diameter holes) along the full length of the sign structure. This is to prevent vandals, hidden behind the sign, from dropping objects onto the motorway below. This is a “Safety in design” requirement.

c) The design shall prevent access by vandals to the sign structure and tamper proof fastenings and connections shall be used.

d) A structure with vertical balustrades or other suitable screens which cannot be climbed shall be provided to prevent unauthorised access to the top of the sign structure. Minimum height of this structure shall be 2.4 m from the road surface or highest point of footfall where a person can stand to climb this structure such on top of the bridge kerb or parapet. This structure shall be designed for loading as stated in Clause 11.5 of AS 5100.2.

e) The sign structure shall not restrict access for maintenance and repairs to the traffic barrier. Drilling or coring into prestressed concrete members is NOT permitted. Signs shall be attached with stainless steel or hot dip galvanized bolts.

11.4.2.2 Working with asbestos in existing bridges

a) Designer shall investigate whether any permanent asbestos items have been used in the bridge prior to preparing the concept design proposal for attaching the sign structure to bridge. Refer Section 1.4.6 for procedure to be followed for identification and working with asbestos.
b) If the presence of asbestos is identified in the existing bridge, it may be too costly to attach the sign structure to the bridge. This is due to the high cost of working safely with asbestos. However, if the attachment method does not require working with asbestos, it may be possible to attach the sign structure to the bridge. However, approval from Director (Structures Review and Standards) shall be obtained prior to commencing the concept design.

11.4.3 Aesthetics

Sign support structures shall be aesthetically compatible with other similar structures in the road network.

11.4.4 Materials

a) Concrete shall be to MRTS70 Concrete and steel reinforcement to MRTS71 Reinforcing Steel. Structural steel shall be to standards specified in Section 11.3.4.1.

b) Other materials, not contained in this Technical Specification, shall not be used without the prior approval of Transport and Main Roads. If permitted, the approval letter will contain details of the appropriate standards or codes.

11.4.4.1 Structural steel

Structural steel material shall meet the following requirements:

- All cold formed structural steel hollow sections to AS/NZS 1163 Grade XXXL0 where XXX is the grade of the steel.
- Steel members fabricated from rolled plates with seam welds need to be designed taking into account the tolerance of rolling in the design. The tolerances are outlined in MRTS63 Cast-In-Place Piles. Rolled plates shall be manufactured in accordance with MRTS63 Cast-In-Place Piles using Grade XXXL15 material to AS/NZS 3678 where XXX is the grade of the steel. All of these welds shall be 100% ultrasonically tested.
- All hot rolled steel plates shall be to AS/NZS 3678.
- All structural steel hot rolled sections shall be to AS/NZS 3679.1.
- Structural steel welded sections shall be to AS/NZS 3679.2.
- Minimum steel thickness for structural steel members shall be 2.5 mm except for external steel members exposed to weather where the minimum steel thickness shall be 3 mm.
- Structural steel water pipe manufactured to AS 1579 is not permitted unless it is tested along the longitudinal axis to AS/NZS 1163 and is Grade xxx L0 where XXX is the grade of the steel.
- Spirally wound fabricated circular hollow sections are not permitted.

11.4.4.2 Bolts, nuts and washers and safety cables

a) Steel bolts, nuts and washers shall be in accordance with MRTS78 Fabrication of Structural Steelwork.

b) Self-tapping screws are not permitted to use in structural connections and to connect sign screen components to the structure. Bolted connections with two nuts in predrilled hot dipped galvanised holes shall be used to connect structural members. In addition to bolted connections, safety cables shall be provided to secure every advertising sign screen cabinet to structural members. The minimum factor of safety for the cable system shall be 5.0 to resist
11.4.5 Structural design
11.4.5.1 Design life

The design life for advertising sign structures shall be 40 years. However, if advertising signs are attached to a bridge, all fasteners attached to the bridge shall be 100 year design life.

11.4.5.2 Live load

Sign structures that have a maintenance platform shall be designed for live loading of 5 kN concentrated moving load over 1 m² simultaneously with 2.5 kPa distributed load elsewhere. The platform shall also be designed for concentrated load of 1 kN over 300 mm square patch located anywhere on the platform floor.

11.4.5.3 Wind loading

a) Wind load shall be calculated in accordance with AS 1170.2 with wind perpendicular and at 45 degrees to the sign face. Drag force coefficient Cd shall be in accordance with AS 1170.2.

b) ARI for ultimate limit state wind speed shall be 2000 years. ARI for serviceability limit state wind speed shall be 20 years.

11.4.5.4 Design for Ultimate strength

Ultimate strength structural design shall be to AS 5100.

11.4.5.5 Structural design criteria for fatigue

11.4.5.6 Attachment to prestressed concrete members

Drilling and coring into prestressed concrete members is not permitted.

11.4.5.7 Load combinations

a) Load factors and load combinations for structural design shall be to AS 5100.

b) When an advertising sign structure is attached to a bridge over road, the design live load for assessing the bridge structure shall be the original design loads used in the design of the bridge.

c) The impact load on the barrier shall be assessed using the Road Barrier Performance Level Selection Method in AS 5100.1. The result from this shall be used to determine whether it is justified to use the barrier impact load that the structure was originally designed for. Also refer to Chapter 7 “Matters for Resolution to AS 5100” Item 19 for the procedure and requirements to determine the barrier performance level.
For comparison, the barrier impact load in the Bridge Design codes is as follows:

**NAASRA 1976** - 45 kN (working transverse outward load)

**Austroads 1992** - 90 kN (ultimate transverse outward load) for \( h < 850 \text{ mm} \)

**AS 5100.2**

- Low performance 125 kN (ultimate transverse outward load)
- Regular performance 250 kN (ultimate transverse outward load).

d) For bridges designed in accordance with the NAASRA or Austroads Codes, the minimum barrier impact load to be used for assessing the bridge structure in combination with the load effects of the advertising sign attached to the bridge, shall be 60% of Low performance, that is 62 kN minimum impact load.

e) For bridges designed in accordance with AS 5100, the full impact load stipulated by AS 5100 for appropriate barrier performance level shall be used for assessing the bridge structure in combination with the load effects of the advertising sign attached to the bridge. Designer shall determine the appropriate barrier performance level in accordance with the AS 5100.1 Appendix B.

f) For bridges designed prior to 1976, these are considered as special cases and the appropriate barrier impact load shall be discussed with Transport and Main Roads Director (Structures Review and Standards).

g) The sign structure Designer shall check the structural adequacy of the bridge structure. Following additional load combinations for ultimate design shall be considered:

i. Combination 1: Ultimate 2000 years ARI wind on sign plus ultimate dead load (bridge and sign structure), no traffic load on the bridge, no vehicle impact on the barrier.

ii. Combination 2: 10 years ARI serviceability wind on the sign plus ultimate dead load (bridge and sign structure) plus ultimate vehicle impact load on the barrier, no traffic load on the bridge.

iii. Combination 3: 20 years ARI serviceability wind on sign plus ultimate dead loads (bridge and sign structure), plus ultimate traffic loads on the bridge, plus serviceability live load on the sign structure working platform, no vehicle impact on barrier.

### 11.4.5.8 Serviceability deflection

The self-weight, live loads and serviceability wind loads shall be taken into account for deflection calculations. The deflection calculations for all structures shall include the long term creep deflection resulting from the foundation movement. Deflection criteria for portal and cantilever structures are provided in Tables 11.4.5.8(a) and 11.4.5.8(b).

**Table 11.4.5.8(a) – Deflection criteria for portal structures**

</table>

* Maximum span for cantilevered gantries shall not be greater than 9.5 m, from centreline of the column to the end of the horizontal arm.

11.4.5.9 Vibration

Vibration limits shall be in accordance with AS 5100 and the Sign Licensee’s requirements for each particular device and screen.

11.4.5.10 Foundation design

a) Foundation design for sign structures shall be based on specific foundation investigation at the sign location to a minimum depth of one full height of the structure unless otherwise directed by appropriately experienced RPEQ (Geotechnical) Engineer. The RPEQ certified Geotechnical report shall include advice to ensure that long term foundation rotation does not result in column deflection in excess of the serviceability deflection limits specified in Section 11.4.5.8.

b) The geotechnical investigation shall identify potential Acid Sulphate Soils. The Designer shall use MRTS51 Environmental Management and MRTS04 General Earthworks to specify the treatment of Acid Sulphate Soils if this is present on the site.

c) Foundation structures such as pile caps, footings and so on, shall be located below the ground with the top of the pile cap, footing and so on, at the same level as the surrounding ground surface level.

d) Suitability of the type of foundation shall be assessed by the structural Designer in consultation with the Geotechnical Engineer.

11.4.5.10.1 Foundation types acceptable for roadside advertising signs:

a) Cast-In-Place piles to MRTS63 Cast-In-Place Piles or MRTS63A Piles for Ancillary Structures as applicable.

b) MRTS63A Piles for Ancillary Structures is applicable for piles for high moment low axial load applications such as single cast-in-place piles. Piles in pile group where axial load is dominant due to the moment couple shall be in accordance with MRTS63 Cast-In-Place Piles.

c) Prestressed concrete driven piles to MRTS65 Precast Prestressed Concrete Piles.

d) Spread footings.

Any other foundation types shall be agreed with Transport and Main Roads (Structures) prior to start of design.
11.4.5.10.2 Foundation types not permitted for roadside advertising signs:

a) The following foundation types are not accepted for use in foundations, for advertising structures above carriageway or those located above a railway:
   - steel screw piles
   - Continuous Flight Auger (CFA) piles
   - precast reinforced concrete piles
   - steel piles (except for Western Queensland, refer Clause 4.1.6)
   - precast concrete piles manufactured by spinning or rolling
   - piles constructed with bentonite or polymer slurry, and
   - bored piles without permanent steel or concrete liners.

b) Any Proponent, who believes the use of such piles is cost effective and will achieve the strength and durability required, may prepare a written submission for assessment by Transport and Main Roads' Director (Structures Review and Standards). Delays in assessing such submissions, and any consequent costs are entirely the responsibility of the Proponent. The department’s publication Engineering Innovation outlines the steps involved in the innovation process, which takes time and should ideally be done outside of a Contractual situation, at the concept design stage.

c) The foundations shall be designed so that the base plate is installed as close to ground level as possible while providing for drainage and other requirements. The design length of the support columns shall take into consideration the variations in the reduced levels of the foundations.

11.4.5.11 Anchor bolt details

On the basis of NCHRP reports and learning from interstate sign structure failures, the following shall be observed:

a) Connections using Class 4.6 bolts are less likely to be controlled by fatigue requirements than are those which use Class 8.8 bolts; however either class may be used provided that the design satisfies both ultimate strength and fatigue life requirements. Class 4.6 and 8.8 bolts shall conform to Transport and Main Roads Technical Specification MRTS78 Fabrication of Structural Steelwork.

b) Pre-tensioned bolts are not warranted.

c) Nut tightening and the use of lock nuts are important to prevent nut loosening, which in turn will cause undesirable larger stress fluctuations, thus increasing the risk of fatigue failure.

d) Snug tightening is adequate for fatigue performance provided it is done properly and provided lock nuts are:
   - purpose made half height nuts
   - made from softer steel than the ordinary nut, and
   - located between the ordinary nut and the base plate.
e) The maximum unsupported length of the anchor from top of footing to the bottom of the base plate shall be not more than one anchor diameter.

11.4.5.12 Base plate thickness

The base plate shall be at least as thick as the anchor bolt diameter.

11.4.6 Corrosion protection and durability

a) The minimum protection of all steelwork shall be either painted or hot-dip galvanised to AS/NZS 4680 including all internal surfaces of circular members.

b) If the steelwork is hot dipped galvanized then:
   - Connections shall be sealed on all faces to stop the ingress of water and galvanising acids which causes corrosion at interfaces. Where access for welding is available to one side of a joint only, a full penetration butt weld shall be used.
   - Where backing bars/backing rings are used inside members, the backing bars/backing rings shall be removed prior to galvanising. If they are not removed, acid is trapped between the backing bars/rings and the member resulting in crevice corrosion.
   - The size of the components shall be checked to ensure that they can be hot-dip galvanised after fabrication. Double dipping shall be allowed.

11.4.7 Concrete durability

The exposure classification for the purpose of determining cover to reinforcement shall be to AS 3600. Minimum exposure classification shall be A2.

Also refer to Clause 3.8.4 for additional requirements of concrete durability.

11.4.8 Maintenance platform

a) Unless specifically nominated otherwise by Transport and Main Roads, all structures supporting advertising signs shall be provided with an access platform to allow maintenance of the equipment and structural components without disrupting traffic.

b) The maintenance platform shall comply with AS 1657 and additional criteria stated in this document. Maintenance Platform shall be provided for the full length of the overhead structure. The minimum width of the maintenance platform shall be as specified by the sign owner provided that the minimum width requirement stated in AS 1657 is satisfied.

c) All walkways and platforms shall have permanent plates secured and displayed in a prominent position stating the maximum design loads for the walkways and platforms and any constraints to loading intensity. These plates shall be detailed on the drawings conforming to the appropriate Australian Standards.

d) Floor of the maintenance platform shall be a grated floor to comply with AS 1657 Clauses 3.2.3 Flooring materials and 4.3 Platform surfaces. The floor shall have a non-slip finish and be self-draining. The “Weldlok” A40-205 floor grating is acceptable to Transport and Main Roads. A protection mesh shall be fitted on to the top of the grated floor to protect objects, maintenance tools and equipment from falling onto the area below. Gaps larger than 10 mm at the ends of the floor which permit items to fall on to the area below shall be fitted with the mesh. The protection mesh shall be an expanded metal with the minor axis not
exceeding 10 mm and minimum thickness of 1.6 mm. “Mastermesh Industries” LD1616 mesh is acceptable to Transport and Main Roads.

e) Guardrailings shall be provided on the maintenance platform. Guardrailings shall comply with AS 1657 Clause 4.4 Guardrailining and have:

- top of the top rail at 1100 mm height from the floor
- one or more middle rails having a maximum clear distance of 450 mm between the rails and a maximum clear distance of 450 mm between the lowest rail and the top of the toe board
- a toe-board which shall not be less than 100 mm above the top of the floor. Toe-board shall be provided all around the floor of the platform except at the platform entrance. Toe-board shall be made using structural steel angle of minimum 3 mm thick
- a protection mesh made from expanded metal mesh with the minor axis not exceeding 10 mm and minimum thickness of 1.6 mm to infill between all the rails and top of the toe-board to ensure that objects, maintenance tools or equipment cannot fall on to the area below. “Mastermesh Industries” LD1616 mesh is acceptable to Transport and Main Roads
- no gaps greater than 50 mm (with or without a mesh) between ends of the guard railing and the structure.

f) Any vertical gaps between the floor of the maintenance platform and the rear of the sign face shall also be fitted with a mesh similar to the mesh fitted with the guardrail to prevent objects, maintenance tools and equipment from falling to the area below.

g) Unless otherwise specified, access to the maintenance platform shall be by fixed ladder systems from ground level designed and installed to:

- AS 1657 Fixed platforms, walkways, stairways and ladders – Design, construction and installation
- AS/NZS 1891 Industrial fall-arrest systems and devices – harnesses and ancillary equipment
- Safe Work Australia Code of Practice
- WHS legislations, and
- additional criteria stated in this document.

11.4.9 Access ladder and landings

a) The ladder system and the landing shall be designed and installed in accordance with AS 1657. The access structure must be considered as a workplace, and the access provisions must conform to the appropriate Act and Regulations. The access must be secured and ensure unauthorised persons cannot obtain entry to the structure.

b) The requirement of intermediate landing, ladder cage and safety harness based fall arrest system shall be in accordance with AS 1657 and Table 11.4.9(a).
Table 11.4.9 (a) – Details of the fall protections

<table>
<thead>
<tr>
<th>Structure type</th>
<th>Fall distance</th>
<th>Fall protection provisions</th>
<th>AS 1657 reference clauses</th>

</table>
| Ladder is within four post gantry column | Up to 6.0 m | - Ladder cage  
- For existing structures, If ladder cage is not possible, a harness based fall-arrest system to AS/NZS 1891 (series) shall be provided. | Clause 7.4.7: Note 2 |
| | > 6.0 m | - Ladder cage, and  
- Intermediate landing at maximum of 4.5 m height. Vertical height between landings in multiple flight ladders should be equal.  
- For existing structures, If ladder cage is not possible, a harness based fall-arrest system to AS/NZS 1891 series shall be provided. | Clause 7.3.6, 7.4.7 and Table G1 (rung type ladder – twin stiles)  
Clause 7.3.6: Note 2 |
| Ladder is fixed other than four post gantry columns. e.g. Single post structure | Up to 6.0 m | - Ladder cage  
- For existing structures, If ladder cage is not possible, a harness based fall-arrest system to AS/NZS 1891 (series) shall be provided. | Clause 7.4.7: Note 2 |
| | > 6.0 m | - Ladder cage, and  
- Intermediate landing at maximum of 4.5 m height. Vertical height between landings in multiple flight ladders should be equal.  
- For existing structures, If ladder cage is not possible, a harness based fall-arrest system to AS/NZS 1891 series shall be provided.  
Omit intermediate landing where installation of intermediate landing is “not reasonably practicable” (Example: A single post VMS structure where an intermediate landing will fall within the working width or over the carriageway). A harness based fall-arrest system to AS/NZS 1891 series shall be provided. | Clause 7.3.6, 7.4.7 and Table G1 (rung type ladder – twin stiles)  
Clause 7.3.6: Note 3 |

- c) When intermediate landing with multiple ladders are used, the ladder arrangement shall be in accordance with AS 1657.
- d) Fall arrester harness systems shall comply with AS/NZS 1891. The harness system shall be capable of arresting falls within a short drop of not greater than 600 mm. The Designer shall be responsible for nominating the type of harness and providing attachment points in the structure. The approved fall arrester system shall have Certification and Approval to AS/NZS 1891 (series).

Table 11.4.9 (b) and Figure 11.4.9 show the details of the fall arrester system manufactured by SafetyLink Pty Ltd which is acceptable to Transport and Main Roads.

Following additional requirements shall also be met:

1. At the bottom of the ladder, the following sign and the wording shall be attached.

![Sign with text: THIS LADDER SHALL BE USED ONLY BY SUITABLY TRAINED PERSONNEL USING AN APPROVED PROTECTION DEVICE.]

SAFETY HARNES MUST BE WORN

1. The base of the ladder shall be kept above the base slab for improved durability. The height to the first rung from base slab shall be not greater than the standard rise. All rises shall be equal except that the first rise may be less than the standard height.
2. Screens shall be provided around the outside of the ladder to prevent children and unauthorised persons accessing the ladder from the gap between the column and the back of the ladder.

3. All other requirements of AS 1657 shall be strictly adhered to, and are not open to interpretation.

4. Following erection a competent person (as defined in the Work Place Health and Safety Act 2011) shall be engaged by the gantry supplier to carry out an inspection and comprehensive safety audit of the gantry for compliance with AS 1657 and WHS legislations prior to handover to Transport and Main Roads.

6. The sign supplier shall provide a metal Plate with the Sign Identification number embossed on it and securely attach it to the structure with vandal proof fastenings.

11.4.10 Wiring and wiring enclosures

a) All wiring and wiring enclosures for installation of power cables must comply with AS/NZS 3000 and the relevant Transport and Main Roads Technical Specifications.

b) All wiring enclosures for telecommunications cables must comply with AS/ACIF S009 and the relevant Transport and Main Roads Technical Specifications.

c) Conduits must comply with Transport and Main Roads Technical Specification MRTS91 Conduits and Pits.

11.4.11 Access to the structure site

a) The design must incorporate a path from where maintenance personnel can park a vehicle and gain access to the structure. Access to the structure site shall be designed to ensure that maintenance personnel can access the structure safely. Routine operation and maintenance access to the structure shall not require traffic control measures, and/or lane closures.

b) Provision shall be made for impact protection of maintenance personnel from errant vehicles.

11.4.12 Protection of structures from vehicle impact

Refer Section 10.12 for the requirement of the protection from vehicle impact.

11.4.13 Transport and Main Roads review of drawings and scheme documents

This clause illustrates the approval process for “On-carriageway” signs and supporting structures.

a) The drawings, specifications, design report, safety in design report and geotechnical report shall be submitted to Transport and Main Roads by the Sign Licensee. These documents are to be reviewed by Transport and Main Roads for safety, durability, future performance, constructability and maintenance. Drawings and other documents shall be submitted for Transport and Main Roads review at 15% preliminary design, 50% substantial completion (unchecked drawings), 85% complete, (checked drawings) and RPEQ certified drawings for final approval. Drawings shall comply with the Transport and Main Roads Drafting and Design Presentation Standards, Volume 3, Structural Drafting Standard.
b) The preliminary design submission shall involve a meeting between Transport and Main Roads (Structures) and the Sign Licensee’s RPEQ engineer to discuss the drawings. The drawings shall include all typical project details. The design shall not proceed until the issues are resolved.

c) Transport and Main Roads will provide comments that the Designer must consider, and these shall be included in the design. If the comment is not acceptable to the Designer, reasons shall be discussed with Director (Structures Review and Standards). The final decision acceptable to Deputy Chief Engineer (Structures) shall be reached. This solution shall be adopted.

d) Fabrication shall not begin until RPEQ certified drawings have been submitted to Transport and Main Roads and approved by the department. Fabrication shall not begin until all hold points and witness points in MRTS78 Fabrication of Structural Steelwork are released by Transport and Main Roads.

For information regarding technical advice for acceptance of advertising signs refer to:

Director (Structures Review and Standards)
Department of Transport and Main Roads
Structures Division
GPO Box 1412
Brisbane Qld 4001

11.4.14 Quality assurance in the documentation

a) Structural design shall conform to a high level of technical competence and shall be based on proven methods, materials and technology. All structures shall be designed in accordance with good engineering practice, relevant codes and incorporate safety in design principles. All structures must have an attractive appearance appropriate to their general surroundings and any adjacent structures. The design shall be practical and cost-effective to construct and maintain.

b) Designer shall be a RPEQ or supervised by an experienced RPEQ structural engineer.

c) Design shall be checked by a structural engineer who is a RPEQ structural engineer. The engineer who undertakes the check shall be different to the Designer and shall do independent calculations.

d) All Engineering Drawings shall be certified by an appropriately experienced RPEQ. The RPEQ Engineer shall also certify on the drawings that the design complies with the relevant Australian Standards relating to Workplace Health and Safety.

e) The Design Report shall contain the following information.

- maximum horizontal and vertical serviceability deflections of the structure
- installation procedure for the structure, including erection procedure of the structure, and
- design considerations for Provisions for Safe Maintenance.

f) The Sign Licensee shall provide a separate report comprising their Structural Inspection and Maintenance Program, and Reporting Format to Transport and Main Roads Structures for review. These shall include defect classifications and remedial measures for each type of defect. The inspection frequency shall be specified in the document.
Chapter 11: Roadside advertising signs

g) Drawings are to incorporate the following details or notes:

- Sign structure location including the location relative to the road edge and nearest property boundaries shall be clearly marked on the drawings. The closest horizontal clearance from the outermost edge of the trafficable lane shall be shown in the drawings. Where the sign structure is above the traffic lanes, minimum vertical clearance above the carriageway shall be shown in the general arrangement drawings.

- All design loads for the structure are to be shown on the drawings. Walkways and platforms shall have permanent plates secured and displayed in a prominent position stating the design loads for the walkways and platforms. These plates shall be detailed on the drawings.

- Material standards, design standards and relevant Transport and Main Roads Technical Specifications shall be referred in the drawing notes.

- The erection sequence shall include all requirements for tightening of hold-down bolts prior to grouting and prior to attachment of outreach arms.

- Construction drawings should include a diagram showing column offset and outreach pre-camber. Designers should calculate column offset based on provision of a 1 in 40 slope after allowance for long-term progressive foundation movement.

- Use of upper and lower templates for hold down bolts is recommended to ensure a good fit with holes in the base plate. Bending of hold down bolts is not permitted. Use of enlarged bolt holes is not recommended.

- Impact protection from errant vehicles.

- Drainage water shall be directed away from the footings of cantilever sign structures to prevent softening of the surrounds and corrosion of base plate and holding down bolts. Concrete paving with or without drainage channels may be appropriate in some areas.

- All welds are to be detailed on the drawings and weld symbols shall be in accordance with AS 1101.3.

- All access holes for cables and wires shall be fabricated without sharp edges to prevent damage to insulation when the cables are drawn.

- No additional holes are permitted to be drilled that are not shown on the RPEQ certified drawings without approval from the Structural Designer.

- Adequate vent holes for galvanising process shall be detailed in the drawings.

- Only those welds shown on the drawings are permitted. No weld is to be omitted or added without the specific approval from the Designer.

11.4.15 Design certification

- Design Certification is required for each sign structure.

- A geotechnical design report, certified by an experienced RPEQ Geotechnical Assessor, shall be included in the Final Design Report for each sign structure.

- A structural design report, certified by an experienced RPEQ Structural Engineer, shall be included in the Final Design Report for each sign structure.
11.4.16 Acceptance for fabrication and construction

On completion of the Department's final review, an acceptance letter will be issued to the Sign Licensee. Fabrication and construction shall not be commenced until the design is approved by Transport and Main Roads.

11.4.17 Fabrication of structural steelworks and aluminium components

a) Fabrication of the structural steelwork shall be to MRTS78 Fabrication of Structural Steelwork.

b) Fabrication of aluminium components shall be to MRTS79 Fabrication of Aluminium components.

c) All structural steelwork and all aluminium work shall be inspected by an appropriately experienced RPEQ Engineer or their approved delegate who is experienced in the fabrication of structural steelwork and ensure all the requirements of the specification are met.

d) All hollow sections shall be joined using full penetration butt welds. Fillet welds are not acceptable for this application as they encourage crevice corrosion resulting in premature failure.

e) The inspections shall be carried out during the fabrication process. The following documentation shall be supplied to Transport and Main Roads with the sign structure:

   • Inspection Report outlining the welding procedures provided match the welds specified on the approved RPEQ Engineering drawings.
   • Inspection Report outlining the review of the material test certificates to show compliance with the appropriate Australian Standards specified on the approved RPEQ Engineering drawings. The report shall state the member size and grade used in the structure. The report shall also outline the heat number and material test certificate number for the material supplied.
   • Inspection Report outlining which butt weld preparations were inspected. This report shall include photos of each type of butt weld inspected with a bevel gauge showing the joint matches the approved welding procedure sheet.
   • Inspection Report outlining the completed welds which have been inspected. The report shall show the welds inspected with the appropriate weld fillet gauge to show the conforming welds and the report shall show any welding defects identified in the inspection.
   • Inspection Report outlining the non-destructive testing carried out in accordance with the specification.

11.4.18 Installation of the structure

a) Sign installation shall be undertaken by a Contractor who shall operate and maintain a quality management system audited by a third party organisation in accordance with AS/NZS ISO 9001 or ISO 3834.

b) Installation shall be in accordance with Transport and Main Roads Technical Specifications.

c) Administrator is responsible for RPEQ certification for releasing Witness Points and Hold Points referred to in the relevant Transport and Main Roads Technical Specifications. This certification shall include below:
Setting out and Excavation

- Structure location shall be set out on the Site by an experienced surveyor. This Witness Point shall be released and certified by the Administrator.

- During the setting out process, the Contractor shall be deemed to have checked the location and details of all structural members in relation to the dimensions of such members.

- If an error in the details shown in the project drawings is detected, the Administrator shall be notified immediately and construction shall not be carried out until written agreement is issued by the Administrator.

- The construction of piles, footings, pile caps, and so on, shall be carried out to the details shown in the drawings and in accordance with the relevant Transport and Main Roads Technical Specifications.

- Prior to concreting, excavated foundations shall be inspected by the experienced Geotechnical Assessor and RPEQ certified.

- Excavation for footings and pilecaps shall be in accordance with the requirements of Clause 14 of MRTS04 General Earthworks.

- Acid sulphate soils shall be treated in accordance with MRTS51 Environmental Management and MRTS04 General Earthworks.

Cast-in place piles

- Cast-in place piles shall be in accordance with MRTS63 Cast-In-Place Piles or MRTS63A Piles for Ancillary Structures as applicable and all Hold Points in MRTS63 Cast-In-Place Piles and MRTS63A Piles for Ancillary Structures shall be released and certified by the Administrator.

Precast prestressed concrete piles

- Precast prestressed concrete piles shall be in accordance with MRTS65 Precast Prestressed Concrete Piles. All Hold Points and Witness Points in MRTS65 Precast Prestressed Concrete Piles and Hold Point (approval to place concrete in first member) of MRTS73 Manufacture of Prestressed Concrete Members and Stressing Units shall be released and certified by the Administrator.

Dynamic testing of piles

- Dynamic testing of piles shall be in accordance with MRTS68 Dynamic Testing of Piles. All Hold Points and Witness Points in MRTS68 Dynamic Testing of Piles shall be released and certified by the Administrator.

Concreting

- Concreting shall be in accordance with MRTS70 Concrete. All Hold Points and Witness Points of MRTS70 Concrete shall be released and certified by the Administrator.
Steel reinforcing

- Fabrication and placing of steel reinforcement shall be in accordance with MRTS71 Reinforcing Steel. All Hold Points and Witness Points in MRTS71 Reinforcing Steel shall be released and certified by the Administrator.

Structural steelwork

- Fabrication of structural steelwork shall be in accordance with MRTS78 Fabrication of Structural Steelwork. All Hold Points and Witness Points in MRTS78 Fabrication of Structural Steelwork shall be released and certified by the Administrator.

Aluminium works

- Fabrication of aluminium components shall be in accordance with MRTS79 Fabrication of Aluminium Components. All Hold Points in MRTS79 Fabrication of Aluminium Components shall be released and certified by the Administrator.

d) Transport and Main Roads does not permit the use of levelling nuts to support the structure. The structure shall be supported by proprietary non-shrink mortar with uniform distribution of the load over the whole plan area of the base plate. An acceptable procedure is as follows:

- stand the column section and level the column by placing a minimum of four steel wedges under each base plate
- mix the non-shrink mortar to a trowelable consistency
- pack the mortar and ensure that the mortar extends over the full area of the base plate
- wait for the mortar to set sufficiently to support the weight of the structure
- remove the steel wedges
- tension the bolts, and
- repair the mortar where the wedges were located.

e) Bolts with T/B or T/F classification shall be tensioned in accordance with MRTS78 Fabrication of Structural Steelwork.

f) All materials and bolts shall conform to the requirements of Transport and Main Roads Technical Specification MRTS78 Fabrication of Structural Steelwork.

11.4.19 Inspection of the installed sign structure

a) Large advertising signs that could fall onto the traffic lanes in the event of a structural failure such as gantries with signs over traffic lanes, cantilevers and butterflies (cruciform) as well as tall light masts and large signs with truss supports in close proximity to the traffic lanes are to be recorded in the inventory of the Bridge Information System (BIS) and will be subject to the inspection regime defined in BAM Support Advice Note No.112: Large Traffic Management Signs-Inventory Creation & Inspection.

b) Sign Licensee shall arrange for the Transport and Main Roads Level 2 routine inspection for the sign structure. Inspection report including the condition of the structure and any defects identified shall be provided to Transport and Main Roads annually.

c) The cost for inspections shall be borne by the Sign Licensee.
11.5 Design criteria for off-carriageway advertising signs

This criteria shall be applied for sign locations stated in Section 11.1.

11.5.1 Vertical clearance

Minimum of 2400 mm vertical clearance above the ground level to the underside of the sign face or any structural component shall be maintained to prevent collision with pedestrians.

11.5.2 Materials

a) Concrete shall be to AS 3600. Steel reinforcement shall be to AS/NZS 4671 and ACRS (Australian Certification Authority for Reinforcing Steel) certified. Structural steel shall be to standards specified in Clause 11.5.2.1.

b) Other materials, not contained in this document, shall not be used without the prior approval of Transport and Main Roads. If permitted, the approval letter will contain details of the appropriate standard or code.

11.5.2.1 Structural steel

Structural steel material shall meet the following requirements:

- All cold formed structural steel hollow sections to AS/NZS 1163 Grade XXXL0 where XXX is the grade of the steel.

- Steel members made from rolled liners with seam welds need to be designed taking into account the tolerance of rolling in the design. Rolled liners shall be manufactured using Grade XXXL15 material to AS/NZS 3678 where XXX is the grade of the steel. Welding shall be carried out in accordance with the provisions of AS/NZS 1554.1. All longitudinal and transverse welds shall be made with full penetration butt welds. Where field joints between lengths are required, they shall employ full penetration butt welds. Longitudinal welds along the liner are staggered. The leading edge of the liners shall be reinforced. All of these welds shall be 100% ultrasonically tested. The out-of-round tolerance shall not exceed 5% of diameter of liner. Steel liners shall not exceed a bow of 1% of the length of the pile in any direction. Liners shall be free of any internal steps or ridges.

- All hot rolled steel plates shall be to AS/NZS 3678.

- All structural steel hot rolled sections shall be to AS/NZS 3679.1.

- Structural steel welded sections shall be to AS/NZS 3679.2.

- Minimum steel thickness for structural steel sections shall be 3.0 mm.

- Structural steel water pipe manufactured to AS 1579 is screw unless it is tested along the longitudinal axis to AS/NZS 1163 and is Grade xxx L0 where XXX is the grade of the steel.

- Spirally wound fabricated circular hollow sections are not permitted.

11.5.2.2 Bolts, nuts and washers

a) Standard bolts, nuts and washers shall confirm to following standards.

b) Bolts - Property Class 4.6 to AS 1110 or AS 1111 as relevant. Bolt diameter, thread form and pitch shall be to ISO coarse pitch series to AS 1275 to 8g tolerances.
c) Nuts - Normal hexagonal nuts of property Class 5 to AS 1112. Diameter, thread form and pitch shall be to ISO coarse pitch series to AS 1275 to 8g tolerances.

d) Flat washers - to AS 1237.

e) High Strength Bolts, Nuts and Washers shall confirm to AS 1252. Bolt diameter, thread form and pitch shall be to ISO coarse pitch series to AS 1275 to 8g tolerances.

f) Self-tapping screws are not permitted to connect structural members. Bolted connections with two nuts in predrilled hot dipped galvanised holes shall be used to connect structural members.

g) Self-tapping screws are permitted to fasten cladding only.

11.5.3 Structural design

11.5.3.1 Design life

The design life shall be 40 years.

11.5.3.2 Live load

The design live loads shall be as for the on-carriageway advertising signs stated in Section 11.4.5.1.

11.5.3.3 Wind loading

a) Wind load shall be calculated in accordance with AS 1170.2 with wind perpendicular and at 45 degrees to the sign face. Drag force coefficient \( C_d \) shall be in accordance with AS 1170.2.

b) ARI for ultimate limit state wind speed shall be a minimum of 500 years for rural applications and a minimum of 1000 years for other cases. ARI for serviceability limit state wind speed shall be 20 years.

11.5.3.4 Ultimate strength

Ultimate strength for concrete design shall be to AS 3600 and steel designs to AS 4100.

11.5.3.5 Structural design criteria for fatigue

11.5.3.6 Load combinations

Load combinations for structural design shall be to AS/NZS 1170.0.

11.5.3.7 Foundation design

a) Sign structure shall be designed with a suitable foundation based on specific foundation investigation reported by an experienced RPEQ Geotechnical Engineer. Transport and Main Roads will not restrict the foundation types providing they satisfy following Australian Standards as appropriate:

i) AS 5100 Bridge design - Foundation and soil support structures, and

ii) AS 2159 Piling – Design and installation.
b) The geotechnical investigation shall identify potential Acid Sulphate Soils. The Designer shall use MRTS51 *Environmental Management* and MRTS04 *General Earthworks* to specify the treatment of Acid Sulphate Soils if this is present on the Site.

c) The foundations may be designed so that the base plate is installed as close to ground level as possible while providing for drainage and other requirements. The design length of the support columns may take into consideration the variations in the reduced levels of the foundations.

d) Foundation structures such as pile caps, footings and so on, shall be located below the ground with the top of the pile cap, footing and so on, at the same level as the surrounding ground surface level.

### 11.5.3.8 Anchor bolt details

Anchor bolt design and installation shall be certified by appropriately experienced RPEQ.

### 11.5.4 Corrosion protection and durability

Suitable paint system to meet the specified durability of the structure or hot-dip galvanized.

### 11.5.5 Maintenance platform

The requirements of the maintenance platform are as specified by the sign owner and shall comply with following standards and guidelines. Refer to Section 11.4.5.2 for design live loads.

- AS 1657 *Fixed platforms, walkways, stairways and ladders – Design, construction and installation*
- Safe Work Australia Code of Practice, and
- WHS legislations.

### 11.5.6 Wiring and wiring enclosures

All wiring and wiring enclosures for installation of power cables must comply with AS/NZS 3000 and the relevant Transport and Main Roads Technical Specifications.

### 11.5.7 Protection of structures from vehicle impact

If the post is within the clear zone, the protection shall be in accordance with Section 11.4.12 otherwise as guidelines provided in the Transport and Main Roads *Road Planning and Design Manual 2nd Edition*.

### 11.5.8 Construction specifications

a) The minimum criteria for construction shall be the relevant Australian Standards.

b) The Designer shall prepare construction specifications for the sign structure.

### 11.5.9 Transport and Main Roads design acceptance

This clause illustrates the approval process for off-carriageway advertising signs.

a) There are no Transport and Main Roads reviews for different stages of design except Safety in Design Report stated below. It is the Designer’s responsibility to ensure that the design
conforms to this section of Transport and Main Roads design criteria for Roadside Advertising Signs, Transport and Main Roads Technical Specifications and Guidelines, and WHS Act and Regulations.

b) Any proposed departures from the above, the Designer shall declare these during the design stage and request Transport and Main Roads to consider and accept the departures. Transport and Main Roads Director (Structures Review and Standards) will provide a written response to this request. Any departure can only be adopted if accepted by Transport and Main Roads.

c) On completion of the design, the Sign Licensee shall submit 100% completed RPEQ Certified design drawings, Design Report, Geotechnical Report and Specifications to Transport and Main Roads, together with a Conformance Statement from the Designer.

d) The RPEQ Designer shall provide a Conformance Statement confirming that the design conforms to this section of Transport and Main Roads Design Criteria for Roadside Advertising Signs, Transport and Main Roads Technical Specifications and Guidelines and WHS Act and Regulations. The RPEQ Designer shall provide the Safety in Design Report to Transport and Main Roads for review on completion of the design.

e) If the design does not conform to Transport and Main Roads requirements, the department has the right to reject the design.

11.5.10 Design certification

a) Design certification is required for each sign structure.

b) A geotechnical design report, certified by an appropriately experienced RPEQ Geotechnical Assessor, shall be included in the Final Design Report for each sign structure.

c) A structural design report, certified by an appropriately experienced RPEQ Structural Engineer, shall be included in the Final Design Report for each sign structure.

11.5.11 Fabrication of structural steelwork

a) Sign fabrication shall be undertaken by a Contractor who shall operate and maintain a quality management system audited by a third party organisation in accordance with AS/NZS ISO 9001 or ISO 3834.

b) All hollow sections shall be joined using full penetration butt welds. Fillet welds are not acceptable for this application as they encourage crevice corrosion resulting in premature failure.

c) Structural steel fabrication shall be in accordance with AS/NZS 1554 and supervised by a Transport and Main Roads approved Inspector as per Clause 4.12 of AS/NZS 1554.1. All cost for this Inspector’s services shall be borne by the sign Licensee.

d) Fabrication shall not start until all material test certificates for structural steel, bolts, nuts and washers to relevant standards are available and signed off by the Inspector.

e) Fabrication shall not start until the welding procedures are qualified and signed off by the Inspector in accordance with AS/NZS 1554.
11.5.12 Construction supervision

a) Construction cannot be commenced until the design is certified appropriately experienced RPEQ.

b) Construction and Installation shall be in accordance with the construction specifications and relevant Australian standards.

c) Sign installation shall be undertaken by a Contractor who shall operate and maintain a quality management system audited by a third party organisation in accordance with AS/NZS ISO 9001 or ISO 3834.

d) Construction shall be supervised and certified by an appropriately experienced RPEQ.

e) Structure location shall be set out on the Site by an experienced surveyor. Administrator shall witness the set out structure location and signed off prior to commence excavation or driving piles.

f) All concrete used in the work shall be subject to sampling and testing to provisions of AS 1012. Administrator is responsible to certify whether slum for concrete placement and the target concrete is achieved.

g) No concrete shall be placed in the work until the excavation for foundation to the design levels is witnessed and signed off by the Administrator. Formwork and reinforcement shall be inspected and signed off by the Administrator.

h) The concreting for cast-in-place piles shall not start until RPEQ Geotechnical Assessor inspect and certify the socket and pile base.

11.5.13 Inspection

a) Sign owner shall arrange the routine Level 2 inspection for the sign structure. Inspection report including the condition of the structure and any defects identified shall be provided to Transport and Main Roads annually.

b) The cost for Inspections shall be borne by the Sign Licensee.

11.6 Provisions of fall protection to existing roadside advertising signs

For retrofitting existing signs, if a fall protection system is required, it shall conform to Table 11.6 and AS 1657.
### Table 11.6 – Details of the fall protections (Retrofitting)

<table>
<thead>
<tr>
<th>Structure type</th>
<th>Fall distance</th>
<th>Fall protection provisions</th>
<th>AS 1657 reference clauses</th>
</tr>
</thead>
</table>
| Ladder is within four post gantry column | Up to 6.0 m | - Ladder cage, or  
- If retrofitting of ladder cage is not possible, a harness based fall-arrest system to AS/NZS 1891 series shall be provided. | Clause 7.4.7: Note 2 |
| | > 6.0 m | - Ladder cage, and  
- Intermediate landing at maximum of 4.5 m height. Vertical height between landings in multiple flight ladders should be equal, or  
- If retrofitting of ladder cage and/or intermediate landing is not possible, a harness based fall-arrest system to AS/NZS 1891 series shall be provided. | Clause 7.3.6, 7.4.7 and Table G1 (rung type ladder – twin stiles) |
| Ladder is fixed other than four post gantry columns. e.g. Single post VMS structure | Up to 6.0 m | - Ladder cage, or  
- If retrofitting of ladder cage is not possible, a harness based fall-arrest system to AS/NZS 1891 series shall be provided. | Clause 7.4.7: Note 2 |
| | > 6.0 m | - Ladder cage, and  
- Intermediate landing at maximum of 4.5 m height. Vertical height between landings in multiple flight ladders should be equal, or  
- If installation of ladder cage and/or intermediate landing is not possible, a harness based fall-arrest system to AS/NZS 1891 series shall be provided.  
Omit intermediate landing where installation of intermediate landing is “not reasonably practicable” (Example: A single post VMS structure where an intermediate landing will fall within the working width or over the carriageway) | Clause 7.3.6: Note 3 |

When intermediate landing with multiple ladders are used, the ladder arrangement shall be in accordance with AS 1657.

The addition requirements listed in Section 11.4.9 shall also be met.
11.7 Approval flow charts

**Design requirements for Advertising Devices – on carriageway**

**Planning**
- Apply for road corridor permit
  - Insert email address
- Obtain approval for sign placement using a generic design (TMR contact to facilitate)
- Use TMR Design Standard
- Obtain geotechnical report (RPEQ certified), issue report to:
  - TMR - for information
  - Structural designer – to inform design

**Concept Design**
- Design initial concept in consultation with RPEQ Certifier (Structural)
- Send initial concept to TMR for comment
- Send Safety in design report to TMR for comments
- Obtain TMR review comments, review if required (10 working days)
- Progress detailed design in consultation with RPEQ Certifier
- Obtain TMR review (10 working days)
- Send TMR approved concept designed to:
  - Piling contractor and also Geotechnical report – to inform design
  - Fabricator

**Piling contractor design/casting (if required)**
- Design piles and substructure in consultation with RPEQ Certifier (Geotechnical)
- Seek Geotechnical advice regarding platform design for site plant equipment
- Obtain TMR review comments, review if required (10 working days)
- Design must have been met on pages 1-10
- RPEQ Certified
- Obtain TMR approval
- Send TMR approved concept designed to:
  - Piling contractor and also Geotechnical report – to inform design
  - Fabricator

**Fabricator**
- Develop shop drawings
- For review by the RPEQ Structural Designer
  - Stamp & sign front cover of drawings to say Design must have been met on pages 1-10
- RPEQ Certified
- Obtain TMR review comments, review if required (10 working days)
- Procure material
- Commence fabrication
- Arrange independent inspections for hold points
- Independent Inspector to certify ready for galvanising
- Submit material certificates to TMR for approval
- Send TMR approvals from Independent Inspector

**Site Works**
- Develop a traffic management plan
  - Seek TMR approval
  - Notify Traffic network manager (e.g. Brisbane BMTMC)
- Submit to TMR
  - Environmental Management Plan and Noise & vibration monitoring
  - Seek TMR review and approval
- Attend site handover:
  - TMR to brief on conditions of entry
  - Provide TMR with Survey certificates confirming pile and substructure is set out correct
- Install footings and piles, drive cast piles, if required
  - Assemble structure
  - Certify structure
- Submit to TMR
  - As constructed drawings including pile and substructure founding levels
  - Wave analysis report from piling contractor
- Level 2 inspection will be carried out by TMR to establish a benchmark and prior to handing over the structure at the end of the Licence Agreement

**Maintenance/Inspections**
- TMR will undertake Level 2 inspections as part of its routine bridge inspections
- Licensee will undertake agreed inspections and maintenance

**SUPERSEDED**
Design requirements for Advertising Devices – off carriageway

**Planning**
- Apply for road corridor permit
  - #insert email address#
- Obtain approval for sign placement using a generic design
  - (TMR contact to facilitate)
- Use TMR Design Standard
  - Obtain geotechnical report (RPEQ certified), issue report to:
    - TMR - for information
    - Structural designer – to inform design

**Concept Design**
- Design initial concept in consultation with RPEQ Certifier (Structural)
- Send Safety in design report to TMR for comments
- Progress detailed design in consultation with RPEQ Certifier
- Send TMR approved concept designed to:
  - Piling contractor and also Geotechnical report – to inform design
  - Fabricator
  - TMR

**Piling contractor design/casting**
- Design piles and substructure in consultation with RPEQ Certifier (Geotechnical)
- Seek Geotechnical advice regarding platform design for site plant equipment
  - RPEQ Certified

**Fabricator**
- Develop shop drawings
- For review by the RPEQ Structural Designer
- Stamp & sign front cover of drawings to say 'Design intent has been met on pages x to x'
- Procure material
- Commence fabrication
- Arrange independent inspections
  - Hold Points
    - Fit up
    - Welding
    - Certify ready for galvanising
- Independent Inspector to approve structure for galvanising
- Send TMR approvals from Independent Inspector

**Site Works**
- Develop a traffic management plan
  - Seek TMR approval
  - Notify Traffic network manager (ie Brisbane BMTMC)
- Submit to TMR
- Environmental Management Plan and Noise & vibration monitoring
  - Seek TMR review and approval
- Attend site handover. TMR to brief on conditions of entry
- Provide TMR with Survey certificates confirming pile and substructure is set out correct
- Install footings and piles, drive cast piles, if required
  - Assemble structure
  - Certify structure
- Submit to TMR
  - As constructed drawings including pile and substructure founding levels
  - Wave analysis report from piling contractor

**Maintenance/Inspections**
- Licensee will undertake agreed inspections and maintenance

12 Buried concrete arch design requirements

12.1 Scope
This design criteria is applicable for buried arch structures crossing over waterways, gullies, valleys, roadways and railways.

12.2 Design life and serviceability
Design life of arch structures shall be 100 years with minimum future maintenance. The roof of all arches below ground shall be waterproofed throughout the extrados of the whole roof.

12.3 Quality assurance in design and documentation
   a) The arch designer (arch manufacturer’s designer) shall provide comprehensive project specific documentation, including but not limited to, detailed construction drawings, work method statement meeting design intent, recess and nibs required, backfill material, compaction layers, compaction equipment, reactions at arch footings, sequencing of spandrels and wing walls for construction to all parties including arch foundation designer and contractor.
   b) The designer of the arch foundation and earthworks is responsible for the inclusion of arch design assumptions provided by the arch designer into the documents for the design and construction of arch foundation, and provide RPEQ certification of the foundation design by appropriately experienced engineer.
   c) The arch designer shall provide RPEQ certification of the arch design by an appropriately experienced engineer.
   d) The arch designer shall provide a letter signed by RPEQ, stating that the design intent has been incorporated by the designer of the arch foundations, and that associated earthworks has met the design assumptions of their arch design.
   e) The contractor shall prepare a detailed work method statement (WMS) conforming the design intent of the arch and arch foundations. This detailed WMS shall be reviewed by the arch designer and arch foundation designer; and both designers shall provide RPEQ certification prior to commencement of the arch installation.

All of above documents including structural design calculations, detailed construction drawings, detailed work method statements (WMS) certified by an appropriately experienced RPEQ shall be submitted to the Department of Transport and Main Roads Director (Structures Review and Standards) at the concept design stage and subsequent detailed design stages 50%, 85% an 100% for Transport and Main Roads’ review and acceptance. All RPEQ certification shall be provided to Transport and Main Roads’ Director (Structures Review and Standards) at the 100% detailed design stage.

12.3.1 Design acceptance process
   a) If a concrete arch culvert or bridge is part of the original design for a roadworks project, prior to tender, the design shall be submitted to the department for review and acceptance.
b) If a concrete arch is submitted as an alternative during tender, it is the responsibility of the tenderer to ensure the detailed design and drawings are prepared and submitted for departmental review and acceptance at the earliest possible date to avoid construction delays. A minimum of four working weeks is required for the department’s review.

c) If all the required design data is not supplied initially, the Contractor or Manufacturer is responsible for consequent delays.

d) Construction shall not commence before the Departmental Representative has accepted the design, based on input from Transport and Main Roads' Director (Structures Review and Standards).

e) Design submission shall include construction method statement including erection sequence. The erection sequence, including requirements of tightening and grouting of hold-down bolts (if any), shall be clearly shown on the structure specific drawings. The precast elements shall be erected in accordance with the specified sequence.

12.4 Design criteria

a) Buried arch structures shall be designed using soil structure interaction methodology.

b) Stability of arch during construction shall be addressed at design stage. Arch design shall consider all construction stage loading and sequence of erection to ensure the stability of arch components at all stages of construction. Additional requirements for arch stability at construction stages shall be included in the drawings and the design reports. All temporary and permanent supports required during construction shall be designed and RPEQ certified by the permanent works designer.

c) Expected deflections at arch crown and bases (if any) at each construction stages shall be stated on the drawings.

d) Arch components can be damaged during transportation and handling. Designer shall provide method of transportation and handling of the arch components. Lift anchors shall be designed in accordance with MRTS72 Manufacture of Precast Concrete Elements. Lifting anchor details, anchor products and lifting diagram shall be shown in the drawings.

e) Geotechnical requirements in arch foundation design including design methodology, geotechnical investigations, design documentations and so on, shall be in accordance with the Department of Transport and Main Road’s Geotechnical Design Standards - Minimum Requirements document. In addition, the following requirements (stated in this document) shall also be met:

i) Geotechnical assessment on site during construction shall be undertaken and certified by an appropriately experienced RPEQ (Geotechnical Engineer).

ii) Geotechnical boreholes shall be taken at maximum spacing of 10 m along the arch foundation, at each of the arch foundations. The scope of the geotechnical investigation shall enable estimation of upper and lower bounds of foundation stiffness for inclusion in the design, and estimates of bearing capacity and long term foundation settlement.
The arch foundation shall be designed for vertical and lateral loads to support the arch during all phases of construction as well as in service. Good foundation information is very important for the arch performance. An accurate founding conditions shall incorporated into the design drawings.

iii) The arch foundation Designer shall provide the values for predicted vertical differential settlements and horizontal deflections to the arch Designer for design of the arch structure.

iv) The arch foundation design and the arch structure design shall be certified separately by appropriately experienced RPEQ Designers.

v) Structural design shall be in accordance with AS 5100.

vi) Design traffic loads shall be SM1600 and HLP400 in accordance with AS 5100.

vii) All the load cases and load combinations shall be submitted for acceptance for both the construction and the final fill load cases.

viii) The design model of the arch shall incorporate both the vertical and lateral stiffness of the foundation and consolidation effects of the soil above the arch.

ix) The design shall make allowance for differential settlement and foundation stiffness. Issues to be considered include:

   - A large diameter arch on rigid foundation (rock, and so on) with a high fill will have an increased embankment load effect compared with the effect on a “soft” foundation, as the embankment may settle more than the arch. An estimate of embankment compression is required.

   - Stiffness of the foundation. If the arch is designed for rigid foundations but constructed on soft foundation, then the differential movement may generate large shear forces.

x) The design shall model the individual layer, incremental backfilling and compaction. Delivery and placement sequence of backfill is vitally important and any ‘non-standard’ approach to method of backfill delivery and placement shall be indicated on drawings. Otherwise standard backfill delivery and placement sequence would be assumed by the designer.

xi) All the design assumptions shall be specified on the drawings, including:

   - maximum out-of-balance fill difference

   - fill load increments

   - compaction methods and any restrictions on the size of compacting machinery

   - size of construction vehicles and minimum embankment cover before traffic is allowed on the arch

   - design assumption for foundation stiffness and differential settlement, preferably in terms of an acceptable range with maximum and minimum values

   - minimum fill height and properties of the engineered fill material required for the arch

   - the sequence of back filling the arch, and
in addition, reference shall be made to Section 12.5.

xii) The ground reactions at the base of the arch for both the construction and the final load cases shall be submitted.

xiii) The design consultant or manufacturer shall provide comprehensive documentation of the method of erection of the arches (including but not limited to backfill material, type of compaction, any propping required and so on).

xiv) Hydraulic engineering analysis shall be carried out to determine the scour potential of the foundations and all other hydraulic implications. The Hydraulic Report shall be provided to the Department of Transport and Main Roads Director (Hydraulics & Flooding) for review and acceptance.

xv) Piles shall conform to Technical Specifications MRTS63 Cast-In-Place Piles, MRTS65 Precast Prestressed Concrete Piles and MRTS68 Dynamic Testing of Piles as applicable.

xvi) At three monthly intervals during the first nine months of traffic loading, at a minimum of three locations but at a spacing not exceeding 20 metres along the arch, settlement and deflections of the arch structure at the footings, 2/3 height on both sides, and the crown shall be monitored during construction. Reports for every interval shall be provided to Department of Transport and Main Roads Structures, comparing predicted with actual movements. The reports shall include engineering assessment of the structure if these differ from the predicted values.

Survey data shall be obtained on arch behaviour during backfill phase and in the 'as constructed' condition. Otherwise it is always difficult to ascertain or understand if any recorded movement has occurred pre or post construction behaviour without base survey data.

xvii) The joints between all the precast components (such as arch segments, spandrel headwalls, and side walls) shall be sealed with an approved material with sufficient overlap across the joint to prevent loss of fill material and achieve minimal future maintenance. The seal shall comprise bituminous seal and geotextile.

xviii) In high risk situations as assessed by Director (Structures Review and Standards) the spandrel headwalls and wing walls shall be constructed of insitu reinforced concrete, not precast components.

For example the portion of the arch components that can be reached by flood water shall be of insitu reinforced concrete.

The extent of insitu reinforced concrete shall extend from the foundation up to a minimum of one metre above the 2000 year ARI flood height.

xix) Minimum vertical clearance shall be as specified in Table 3.1.2.4 and minimum carriageway width as specified in Section 3.1.1. The minimum vertical clearance shall extend over the shoulder of the road below the arch. The designer shall provide Department of Transport and Main Roads with dimensions of all critical underpass vehicles in their loaded configuration, at the concept design stage for Transport and Main Roads review of clearances.
xx) For mine haul road carrying mine vehicles, the following shall apply:
- "Over height" portal gantries and sensors are required at all approaches. "Maximum height" signage required at approaches and on the arch structure.
- Overhead Gantry that project across trafficked lanes: Protection from Vehicle Impact. The dimensions and foundation of the barriers shall be designed appropriately for the size of the impact vehicle.
- Traffic barriers on the arch shall be designed for the performance level in accordance with AS 5100, with sufficient edge distance from the edge of the road batter. The Department of Transport and Main Roads’ Road Planning and Design Manual and Transport and Main Roads Guidelines shall be used for barriers not located on the arch.

xxi) The concept design for the arch shall be reviewed and accepted by Department of Transport and Main Roads’ Director (Structures Review and Standards) before proceeding to detailed design.

xxii) The requirements for design review by the Department of Transport and Main Roads Structures is the same as for bridges in Department of Transport and Main Roads’ Design Criteria for Bridges and Other Structures guidelines. The arch foundation Designer and arch Designer shall provide their RPEQ certified design reports to the Department of Transport and Main Roads Structures for review and acceptance.

12.5 Other requirements
The Department of Transport and Main Roads Drafting and Design Presentation Standards Manual, Volume 3, Structural Drafting Standards shall be complied with.

12.6 Concrete durability
a) Reference shall be made to Section 3.8.4 for concrete durability requirements.

b) Minimum exposure classification for cover of concrete shall be B2* (Soil face) and B2* (Air face) in accordance with AS 5100. Higher exposure classifications shall be determined on a project specific basis.

c) Concrete strengths, minimum cover and curing conditions shall be detailed in the drawings.

12.7 Development adjacent to arches
“Other additional loads” required for the arch to cater for future changes shall be:

a) additional uniformly distributed working loads of up to 50 kPa acting at ground level

b) natural surface level build-up of up to 1 m with fill equivalent to a uniformly distributed load of 20 kPa

c) any loads from proposed developments above (such as residential, commercial or industrial, etc.), and

d) the allowable maximum difference in level from one side of the arch to the other. A minimum of 0.5 m difference is required.

SUPERSEDED
12.8 Arch manufacturing criteria

Construction shall be in accordance with the department’s Technical Specifications:

- MRTS70 Concrete
- MRTS71 Reinforcing Steel
- MRTS72 Manufacture of Precast Concrete Elements
13 Retaining structures

Typical retaining structure types are:

- Reinforced Soil Structure (RSS) retaining walls
- Embedded retaining walls
- Reinforced concrete cantilever retaining walls
- Soil nail retaining walls
- Gabion retaining walls
- Boulder retaining walls
- Reinforced masonry walls.

13.1 Design requirements for retaining walls

Geotechnical requirements for design including design methodology, geotechnical investigations, design documentations and so on, shall be in accordance with Transport and Main Roads Geotechnical Design Standards - Minimum Requirements. In addition to that, requirements stated in this document shall also be met.

13.2 Design life of retaining structures

The design life of retaining structures is 100 years.

13.3 Design certification

A Design Certification is required for each retaining structure. Refer Transport and Main Roads Geotechnical Design Standards - Minimum Requirements for design certifications for geotechnical designs.

13.3.1 Structural design

a) Structural designs for retaining structures shall be designed and/or supervised by an appropriately experienced RPEQ (Structural Engineer).

b) All structural designs of retaining structures shall be design-checked by or supervised by an appropriately experienced RPEQ. The Engineer who undertakes the check shall be different to the Designer.

c) Structural design for retaining walls including reinforced concrete retaining walls for bridge abutments subject to traffic live loads shall be designed in accordance with AS 5100.2 and AS 5100.3.

d) Draw-down effects must be catered for.

e) Minimum thickness of the shotcrete facing slabs for soil nail retaining walls shall be 160 mm. The cover to reinforcement shall be to AS 5100.5 and cover shall be increased by 30 mm against soil. Minimum concrete for shotcrete shall be 40 MPa.
13.3.2 Design certification – additional requirements

On projects where the Contractor is responsible for the design of retaining wall, the following shall apply:

a) The design documentation shall include a Design Certificate from the Contractor's Designer which confirms that the design of each retaining structure:
   • adequately allows for the site conditions, applied loadings, and relevant material properties for all components of the design, and
   • ensures the structural integrity and serviceability of the wall for the nominated design life.

b) For each retaining wall, the Contractor's Design Documentation shall include the following in addition to the Design Certificate:
   • design calculations
   • Contractor's construction drawings
   • Contractor's construction specifications, including wall construction sequence
   • any particular requirements for ground and/or foundation improvement, and
   • arrangements for monitoring the performance of the wall over the nominated period.

c) The Contractor's Design Documentation shall be submitted by the Contractor to the Departmental Representative and the Verifier prior to commencement of construction of the wall.

d) The Contractor must submit to the Departmental Representative and the Verifier a report certified by the Contractor's appropriately experienced RPEQ (Geotechnical Assessor) who carried out the design of the retaining structure and supervised its construction, that the retaining structure has been duly constructed as per the design specifications and meets all the design requirements, including the foundation bearing requirements.

13.4 Quality assurance for design and construction

a) Prior to any construction, the Contractor must provide evidence to the Verifier that the material proposed to be placed within the reinforced soil block meets the minimum Deed and any requirements specified by the Designer for all material attributes, including the permeability of the material tested at the specified relative dry density.

b) During construction of Reinforced Soil Structures (RSS), regular testing must be undertaken in accordance with Transport and Main Roads Standard Specification MRTS06 Reinforced Soil Structures. The Designer must inspect the site during construction and on completion of the RSS construction, and must certify that the RSS wall has been constructed to the specified design, including the use of materials that conform to the specified parameters.

13.5 Aesthetics

a) Retaining walls (including wall abutments to bridges) must use simple, straight or large radius curved alignments sympathetic to the road alignment and interfaces with adjoining development, pathways, structures and environmental features. Obvious and incongruous kinks and sharp bends must not be evident in wall alignments. Retaining walls are to be finished in modular concrete panels that conform to a consistent patterned design, with an
emphasis on vertical joint lines. Retaining walls are to incorporate integrated design features or separate elements to act as a neat capping feature to the top of the wall and be integrated with other structures and associated urban design treatments used throughout the project works. Fixings for retaining structures must be concealed or integrated as a design feature.

b) All structures must be of uniform colour and surface finish, incorporate defects repair and patching that matches the appearance of the remainder of the surface, and present horizontally and vertically aligned and uniformly patterned formed tie holes in the case of concrete components.

13.5.1 Flood loading

All retaining walls subject to flooding must be designed for the appropriate forces for a 2000 ARI event.

13.5.2 Tiered walls

An upper stepped wall shall be permitted only if the toe of the upper wall is outside the 45° wedge drawn through the heel of the lower wall. The interaction effect of the upper wall on the lower wall shall be considered in the design.

13.5.3 Control joint for prevention of cracks in retaining walls

The Designer shall nominate the spacings for control joints (typically maximum spacing of 4 m) and construction joints to prevent cracking of the wall.

13.6 Retaining wall drainage

Drainage shall conform to Transport and Main Roads Technical Specification MRTS03 Drainage, Retaining Structures and Protective Treatments.

13.7 Design calculations

a) Prior to the construction of any retaining structure, the Contractor must supply to the Verifier and the departmental Representative all calculations associated with that retaining structure.

b) In addition to the requirements in Section 13.8, for RSS Walls the Contractor must supply to the Verifier and the departmental Representative all calculations associated with that retaining structure, together with the duly completed design checklist in MRTS06 Reinforced Soil Structures Appendix which shall be a Hold Point in the Project Plan.

13.8 Additional requirements for Reinforced Soil Structure (RSS) retaining walls

RSSs comprise of precast concrete panels that retain engineered earth fill using steel straps embedded in the fill.

a) Design of RSS walls must be undertaken in accordance with Transport and Main Roads Technical Specification MRTS06 Reinforced Soil Structures. The Designer must inspect the site during and on completion of the RSS construction. The Designer must certify that the RSS wall has been constructed to the specified design, including the use of materials that conform to the specified parameters.

b) RSS retaining walls are not permitted where the water level will be at or above RSS foundation level for any flood event up to 100 year ARI.
c) Where RSS walls are used as the front face of the bridge abutment, the requirements stated in Section 4.5.2 shall also be met.

RSS retaining structures are not designed to resist road / train traffic impact.

13.8.1 Impact protection from Road traffic

a) If RSS wall is located within the 10 m clear zone (measured from the edge of the white marked lanes), RSS walls shall be protected from impact as follows or shall be provided with sufficient redundancy so that the bridge that it supports shall not collapse in the event of a collision.

b) The minimum requirement is a Medium Performance, 1100 mm high single slope concrete barrier to protect the RSS wall from road vehicle impact. The concrete barrier shall be designed with loads in accordance in AS 5100. The concrete barrier shall be separated from the RSS wall to avoid transfer of impact loads to the RSS wall. For this purpose, the minimum clear distance between the barrier and the RSS wall shall be 700 mm based on the 1100 mm working width in accordance with the Transport and Main Roads Road Planning and Design Manual and 200 mm allowance for barrier deflection. Foundation of the protection barrier shall be structurally designed to cater for the deflection of the barrier in the event of a crash within this clearance.

c) If the RSS wall is located outside the 10 m clear zone, no additional protection from impact is required.

13.8.2 Impact protection from rail traffic

a) The minimum requirement is a concrete crash wall designed in accordance with AS 5100 to protect the RSS wall from train impact. The minimum height of the crash wall shall be 3000 mm from the top of the rail track. The crash wall shall be separated from the RSS wall to avoid transfer of impact loads to the RSS wall. For this purpose and access for maintenance, the gap between the crash wall and the RSS wall shall be minimum of 700 mm unless the RSS wall base is located above the top of the crash wall where the impact load will not transfer to the RSS wall. This gap shall be closed at the top of the wall using a suitable cover to prevent unauthorised access into the gap. Adequate drainage provisions shall be provided for possible collection of water within the gap.

b) For Queensland Rail (QR) trains the impact force shall be in accordance with the latest version of QR document Civil-SR-012 - Collision Protection of Supporting Elements Adjacent to Railways.

c) For freight and mine ore haul trains the impact forces shall be determined as appropriate for the particular train details.

d) The concrete crash wall shall extend beyond each end of the RSS wall by at least half the length of a train carriage (QR pedestrian train carriages are typically 25 m long, a six car train is 150 m long), and for mine haul trains the extension of the crash wall shall be half the length of the ore wagon beyond each end of the RSS wall.
13.8.3 Mine haul vehicle impact

a) RSS structures are not designed to resist large vehicle impact of the magnitude associated with mining or similar industries. Bridge abutments (of all types including RSS structures) and piers of bridges shall be protected with a “granular fill” barrier that has been designed to resist vehicle impact through energy absorption without adversely affecting the structural integrity of the abutments and piers. The “granular fill” barrier or “gravel mound” barrier may have vertical faces or battered slopes that form the sides of the barrier.

b) The impact forces shall be derived using the specific vehicle characteristics. The design forces shall be specified on the bridge design drawings including assumed angle of impact, height of impact, vehicle mass and velocity. The properties of the granular fill shall be specified. The design of the barrier system shall be described in the Bridge Design Report.

c) The height of the “granular fill” wall shall be at least the height of the vehicle wheels but not less than 4 m high. The width across the top of the “gravel mound” barrier could be of the order of 5 m approximately depending on the size of the mine truck.

d) Unlike RSS structures that have vertical faces, for abutments that have spill throughs with battered slopes, the design details of the abutment protection from impact could be of a different form to the “granular fill” barrier for RSS walls. The details of barriers at spill throughs need to be discussed with Transport and Main Roads Director (Structures Review and Standards) at concept stage and at peer review stages.

e) The design of the barriers shall consider the ease of repair or replacement when damaged after impact.

f) Clearance height of the over bridge cannot be determined until the proximity of the unloading point relative to the bridge is understood. The truck will ride up onto the sides of the battered gravel mound on impact with the barrier. This increases the required clearance height of the over bridge.

g) The use of steel gantries over the road at each approach is required to prevent excess height vehicles from reaching the bridge. The gantries need to be located well before the bridge approaches to provide ample warning of excess height loads.

h) The use of trucks fitted with anti-acceleration devices to prevent gear changes when the tray is in the raised position, is also a factor in appraising the required vertical clearance under the bridge.

i) The design envelope of the design vehicle and its load under the bridge shall be shown on the drawings.

13.9 Additional requirements for piles in retaining walls

13.9.1 Cast-in place piles for high moment, low axial load applications

Piles for high moment, low axial load applications shall conform to the following:

- The minimum diameter for piles is 600 mm.
- Piles for high moment, low axial load applications shall be designed to conform to MRTS63A *Piles for Ancillary Structures*.
- The design intention is that the piles are cast in the dry.
• Liners shall be used to limit water ingress and to prevent collapse of wall or foundation materials. Acceptance from Transport and Main Roads Director (Geotechnical) shall be obtained prior to use of temporary liners.

• Temporary liners are not permitted in situations with high water table and/or collapsible soils.

• Bentonite or polymer slurry shall not be used.

13.9.2 Contiguous piled walls

Contiguous piled walls shall conform to the following:

• The minimum diameter for piles is 600 mm.

• Foundations for high moment, low axial load applications shall be designed to conform to Transport and Main Roads Technical Specification MRTS63A Piles for Ancillary Structures.

• The design intention is that the piles are cast in the dry.

• Liners shall be used to limit water ingress and to prevent collapse of wall or foundation materials. Acceptance from Transport and Main Roads Director (Geotechnical) shall be obtained prior to use of temporary liners.

• Temporary liners are not permitted in situations with high water table and/or collapsible soils.

• Bentonite or polymer slurry shall not be used.

• Maximum crack width in permanent shotcrete shall be 0.2 mm.

• Shotcrete infill between piles shall be a minimum 160 mm thick, and shall have minimum reinforcement of SL81 mesh. This minimum thickness is for B2 exposure classification with 40 MPa concrete and reinforcement cover to AS 5100. Cover to be increased by 30 mm on soil side.

• Testing of production shotcrete for compressive strength, density, relative density and permeability, including test frequency shall comply with Appendix B82/L of RMS Specification B82 Shotcrete Work.

• Steel Fibre Reinforced Shotcrete shall only be used where accepted in advance by the Director (Structures Review and Standards). Its Toughness shall comply with Clause 3.9 of RMS Specification B82, and test frequency shall comply with Appendix B82/L of RMS Specification B82.

13.10 Additional requirements for block masonry retaining walls

Block masonry retaining walls shall be designed in accordance with AS 3700. In addition to that the following requirements shall also be met:

• minimum reinforcement size for block walls shall be 12 mm spaced at 200 mm maximum centres horizontally and vertically

• minimum reinforcing steel shall comply with Clause 8.4.5 of AS 3700

• all voids shall be infilled with grout with a minimum strength of 40MPa

• the minimum block thickness shall be 190 mm with reinforcing steel is centrally located
• in reinforced masonry walls, the masonry thickness shall not contribute to the reinforcement cover, and

• retaining wall shall have a reinforced concrete base that integral with masonry wall.
14 Busway stations, light rail stations and ancillary structures

14.1 Design life

a) The design life of the structural members shall be:

- 100 years for bridges
- 100 years for all major infrastructure elements that are above the busway, light rail or above a roadway/rail
- 100 years for all elevated parts of the infrastructure not integrally connected to the bus/road bridge (major infrastructure element excludes roofing, glazing)
- 100 years for bus station buildings or similar of more than one storey
- 50 years for bus station buildings or similar of one storey
- 50 years for slab-on-ground buildings, buildings not constructed over road, rail or other transport infrastructure
- 50 years for retaining walls, paths, walkways or similar
- 50 years for bus shelters and other elements that are not over road, busway, rail or transport infrastructure, and
- 50 years for building architectural and fit-out items sub-elements such as windows, glazing, tiles, fascia.

b) 50 years for all other elements. The Designer shall specify the design life of any elements with a design life less than 100 years. The Structures Inspection Manual shall detail the method of replacement of all sub-elements with a design life less than 100 years.

14.2 Materials

14.2.1 Concrete class

a) Normal class concrete may be used for pedestrian slab on ground, retaining wall not supporting road or bus traffic and where the retaining wall is not adjacent to a road or busway.

b) Special class concrete in accordance with Transport and Main Roads Technical Specification MRTS70 Concrete shall be used for all structural members.

14.2.2 Structural steel

Structural steel material shall meet the requirements of Section 4.16.

14.3 Design criteria

a) Design of Busway Stations, Light Rail Stations and Ancillary Structures shall be in accordance with project specific design criteria. These project specific design criteria shall be developed with reference shall be reviewed and accepted by Transport and Main Roads’ Director (Structures Review and Standards).

14.3.1 Column base plate details

a) The detailing of column footings are required to satisfy durability and safety in design considerations. Steel posts shall not extend below ground level because corrosion will occur. For durability reasons, the steel post / column shall end with a base plate above ground.

b) Safety in design considerations mean that anchor bolts at ground level may be a tripping hazard. For example, this hazard may be overcome by ornamental screens to stop people tripping or placing on a raised plinth.

c) Base plates shall be constructed above ground/finished floor level. Base plates shall be left open without embedment into concrete or other material.

14.3.2 Foundation types not permitted by the department

a) The following foundation types are not accepted for use in foundations, to structures above carriageway or those located above a railway:
   - bored piles (without permanent steel or concrete liners)
   - pile constructed with bentonite or polymer slurry
   - driven reinforced concrete piles
   - continuous flight auger piles
   - precast concrete piles manufactured by spinning or rolling, and
   - steel screw piles.

b) Any Proponent, who believes the use of such piles is cost effective and will achieve the strength and durability required, may prepare a written submission for assessment by Transport and Main Roads’ Director (Structures Review and Standards). Delays in assessing such submissions, and any consequent costs are entirely the responsibility of the Proponent. The department’s publication Engineering Innovation outlines the steps involved in the innovation process, which takes time and should ideally be done outside of a Contractual situation, at the concept design stage.

14.3.3 Corrosion protection for structural steelworks

14.3.3.1 General

a) All structural steelworks shall be hot dip galvanised to AS/NZS 4680. Galvanising surfaces may be painted to colours shown in the architectural drawings. Such paint systems shall be compatible and adhesive on to the galvanising surface. Paint systems shall be applied in accordance with the Transport and Main Roads Technical Specification MRTS88 Protective Coating for New Work.

b) Refer Section 3.8.1 for additional requirements for galvanising on steel with low silicon and low phosphorous contents. Following additional requirements shall be met in galvanising of steel works:
   - Connections shall be sealed on all faces to stop the ingress of water and galvanising acids which causes corrosion at interfaces. Where access for welding is available to one side of a joint only, a full penetration butt weld shall be used.
• Where backing bars/backing rings are used inside members, the backing bars/backing rings shall be removed prior to galvanising. If they are not removed, acid is trapped between the backing bars/rings and the member resulting in crevice corrosion.

• The size of the components shall be checked to ensure that they can be hot-dipped galvanised after fabrication. Double dipping shall be allowed.

14.3.3.2 Substitute for hot dip galvanising

Where hot dip galvanising is not possible due to a reason such as limitation of the galvanising bath sizes, zinc metal paint system in accordance with MRTS85A Repainting Existing Steel Bridges and New Steel Bridges Zinc Metal Systems shall be applied subject to prior acceptance from Director (Structures Review and Standards). Following additional requirements shall be met:

a) Any paint system specified must include details of how the coating shall be repainted in the future. The recoat system must be compatible with normal operating systems, for example:

• Abrasive blasting on site is difficult and undesirable.

• The closure of some lanes for repainting is not possible on highly trafficked roads. Similar conditions shall apply to other transport corridors, and/or

• All coatings shall be able to be applied by airless spray, brush, roller, and air. The first coating system shall be applied in the shop. Recoats would be field applications.

b) Any painted steelwork (for example components in gantry or bridge) over a road, rail or shopping corridor shall be provided with a maintenance gantry attached to the structure. The design of the maintenance gantry shall be such that when the maintenance gantry is in use, it will not intrude into the clearance envelope of all surrounding corridors.

c) All bolt, rivets and edges shall be stripe coated.

14.4 Durability for concrete

The minimum exposure classification for the purpose of determining cover to reinforcement and the concrete mix shall be B2 to AS 5100 except exposure classification for components with design life of 50 years or less as specified in Section 14.1 shall be to AS 3600. Minimum exposure classification for components of 50 years or less shall be A2 to AS 3600.

Also refer to Section 3.8.4 for additional requirements of concrete durability.
15 Development application in the proximity to bridges and other structures including transport infrastructures

Refer Chapter 9 for development application in the proximity to tunnels.

15.1 General

Transport and Main Roads is vested with the responsibility to inspect, maintain and operate state-controlled infrastructure. In order to undertake these duties, Transport and Main Roads must make the following provisions:

a) Provision must be made for duplication and widening of the road / transport infrastructure.

b) A corridor of 20 m wide or to the limit of the existing property boundary, whichever is lesser to full length both sides along the infrastructure must be provided as a Transport and Main Roads road reserve.

15.2 Drawings, reports and method statements

The Developer shall submit relevant items from the following list in the form of drawing or report for Transport and Main Roads review:

a) Structural drawings and architectural drawings of the new development showing minimum of but not limited to the following. RPEQ certified structural drawings shall be submitted before commencement of the construction.

- extent of the development relative to the department's assets
- type of development
- general arrangement drawing and the cross section of the new structure
- clear distance to the department's structures from closest structural element of the new development
- foundation details of the proposed structures including the type of foundation, founding levels and the geotechnical design loads such as applied bearing pressure under shallow foundations, pile design loads and so on
- details of temporary anchors into and adjacent departmental properties including the location, anchor loads and so on, and
- construction sequence.

b) Imposed loads on the department's structures due to constructions activities.

c) Impact of development on departmental infrastructure:

Developer shall submit a report explaining the impact of development on Transport and Main Roads infrastructure, if any. Minimum of following areas shall be described in this report:

- Demonstrate that the adequacy of the proposed retaining system to keep the effects of the excavation (and installation of anchors) within allowable limits.

- The sections of foundation of all the adjacent Transport and Main Roads structures (which are within the influence zone of the excavation work and the anchors) in relation to the retaining system (including the wall and anchors). The influence zone can be as much as two times the excavation depth in soft grounds.
Chapter 15: Development application in the proximity to bridges and other structures including transport infrastructures

- The predicted movements of the foundation and the surroundings.
- The effect of Negative Skin Friction (NSF) on pile foundation of the Transport and Main Roads structures. NSF due to dewatering and the excavation induced settlement could be expected on piles within the soft clay.

d) Excavation details including method statement, exclusion zones, machinery used and vibration issues.
e) RPEQ certified temporary works designs including shoring details, pile or anchor arrangements.
f) Soil investigation reports and geotechnical design report including settlement calculations for proposed development and any possible influence on adjacent Transport and Main Roads structures.

15.3 Potholing criteria

a) Potholing, demolition, excavation, installation of services or other construction works within the 20 m wide road corridor or inside the property boundary are not permitted without the written acceptance of Transport and Main Roads prior to commencement of the works.

b) The Developer is required to submit a RPEQ certified design report including detailed drawings of proposed works for Transport and Main Roads review. All details including the construction sequence of the development shall be shown on the plans. All possible effects on Transport and Main Roads structures, design assumptions and proposed mitigations measures shall be clearly demonstrated in the report.

15.4 Demolition phase

a) Explosives shall not be used adjacent to the Transport and Main Roads bridge structures during demolition.

b) Prior to commencement of any construction activity, the Contractor shall undertake a risk assessment for the potential damage to nearby Transport and Main Roads structures. Demolition of buildings or other structures adjacent to Transport and Main Roads structures shall be provided with temporary props.

c) The department's assets in close proximity to the structures subject to demolition must be monitored for displacements, cracks and any effects resulting from demolition.

15.5 Construction phases

During the construction phases including excavation, the following issues are to be addressed by the Developer:

- Dilapidation, vibration, crack growth and soil movement due to the construction activity.
- Instability of the excavation walls adjacent to Transport and Main Roads structures.
- Instrumentation and monitoring:
  - Adequate instruments, namely inclinometers, piezometers, tiltmeters, anchor load cells, settlement markers and prisms shall be provided. This is to verify design assumptions and to monitor the effects on Transport and Main Roads structures due to the excavation and installation of anchors.
• Ground water fluctuations next to Transport and Main Roads structures.

• Installation of permanent anchors into the department’s road reserve for structures on adjacent properties is not permitted.

• Transport and Main Roads may permit temporary anchors to be installed in the departmental property subject to the anchors being sufficiently clear of existing Transport and Main Roads infrastructure so as not to damage it and to avoid transferring additional load effect on it. Developer shall obtain written approvals before installing temporary anchors. The Developer shall de-stress the temporary anchors on or before completion of the development. RPEQ certification of the de-stress shall be submitted to Transport and Main Roads within 28 days of their de-stressing.

• Acceptance to install rock anchors that protrude into the Transport and Main Roads road reserve or within 2 m of the departmental infrastructure shall be obtained prior to undertaking the works.

• Any work adjacent to any Transport and Main Roads infrastructure shall cause no deleterious effect to the departmental infrastructure.

15.6 Additional criteria for development adjacent to bridges

During excavation, explosives shall not be used adjacent to the bridge structures.

No rock blasting shall be permitted during excavation unless the applicant can demonstrate that there is no alternative and approval obtain from Transport and Main Roads Deputy Chief Engineer (Structures). A separate submission shall be required for proposed rock blasting with consideration for mitigating adverse effects on adjacent structures and utilities. This submission shall be submitted to the department for review and approval.

The following additional requirements apply to bridges:

a) No excavation within 10 m of any part of bridge substructure.

b) Where the base of the new excavation is below the founding level of the bridge, no excavation shall be within the limit stated in item a) above. Where battered earth retaining design is adopted, the top of the batter shall not encroach within the 10 m limit referred in a) above. RPEQ certified earth retaining design report and drawings shall be submitted for Transport and Main Roads review in accordance with Section 15.2. Where appropriate, the earth retaining design shall take into account the influence of the loading from the bridge. In this case, the retaining structure shall permanently support the portion of the bridge loads imposed. Any future proposed changes to this retaining structure shall be submitted to Transport and Main Roads for review.

c) 10 m minimum lateral clear distance shall be maintained either side of the bridge from permanent widest parts of the bridge structures as shown in the Figure 15.6(a). This lateral clearance shall be maintained from all areas including underneath of the bridge and for the full length of the bridge foot print.
d) 6.5 m vertical clear height above the highest point of bridge carriageway. Additional provision or buffer in terms of height shall be provided for tunnelling effect, lighting, exhaust fans and signage.

Provision for noise suppression and fire protection shall also be provided for tunnel effect around the structure.

e) Where the bridge columns are located in water and with no land access, horizontal clearance around the bridge columns shall be maintained as shown in Figure 15.6(b) and Figure 15.6(c) as applicable for:

- construction of temporary work platform
- barge access associated with rehabilitation works, and
- underwater inspection of the piles and pile caps.

Within the above horizontal clearance, vertical clearance shall be maintained for possible pile driving for temporary work platforms at every column in the river.

Figure 15.6(b) – Lateral clearance to the bridge columns located closure to river bank

a) Land is perpendicular to the bridge alignment
b) Land is parallel to the bridge alignment

Figure 15.6(c) – Lateral clearance to the bridge columns located away from river bank

a) Land is perpendicular to the bridge alignment

b) Land is parallel to the bridge alignment

f) Additional requirements adjacent to Riverside Express Way (REX) structures are as follows:
   - The existing Queens Wharf Road (QWR) shall be kept for use for maintenance access for REX. When there is no access via the QWR, then a truck and crane access corridor of 6.0 m wide shall be provided between QWR and the Brisbane River Bank for the section of the REX footprint. This corridor shall be continuous straight horizontal alignment without interruptions and kept open for Transport and Main Roads access at all times (24/7).
• Lateral access for truck and crane to the REX Bridge shall be provided via QWR or the new truck and crane access corridor. Lateral access shall be kept open for Transport and Main Roads access at all times (24/7).
16 Design of Fibre Reinforced Polymer (FRP) composite girders

16.1 Scope and application

This section of the design criteria specifies the minimum requirements for the design of FRP composite girders for the following two categories of Transport and Main Roads road bridges:

- Category A: FRP composite girders to be used as superstructure in a new bridge.
- Category B: FRP composite girders that replace timber girders in a timber bridge renewal program.

FRP girders shall be designed in accordance with this section. Additional requirements for Category A girders are contained in Section 16.9 and Category B girders in Section 16.10.

Except where specified, design of FRP girders shall be according to Eurocomp Design Code, refer to Table 1.1.

16.2 Symbols and notations

The symbols and notations used in this section are listed in Table 16.2.

Table 16.2 – Symbols and notations

16.3 Provision for innovation

This section provides for innovation in FRP composite girder design. Adopting innovation allows to capture benefits from rapid changes and evolutions in the FRP composite field.

For this section, the term ‘innovation’ applies to new:

- fibre materials
- resins
- manufacturing processes of fibre composites
- coatings
• development in the fibre composite field, and
• a complete girder.

Above innovative products shall be assessed against this section and comply with the structural performance matrix in Table 16.3. An evaluation process shall be triggered if an innovative product scores an average of four or more on the structural performance scale. The strategy for assessing product innovation is described in *Engineering Innovation*, referenced in Table 1.1.

Submissions regarding innovation are made to the Director (Structures Review and Standards).

#### 7. Inspection

- Easy to inspect critical defects

#### 8. Value for Money

- Short Term Cost: (Material/fabrication/construction)
- Long Term Cost: (maintenance/demolition/disposal)
- Life Cycle Cost:
  - initial cost
  - maintenance cost
  - operating cost
  - replacement and refurbishment cost
  - retirement and disposal costs

#### 16.4 Maximum operating temperature

The maximum operating temperature for structural members, components and system designed shall not exceed \( T_g - 22^\circ C \). \( T_g \) is the glass transition temperature of the composite system. The maximum operating temperature shall be 68°C corresponding to \( T_g \) of 90°C.
16.5 *Exclusions*

Laying of hot asphalt overlay on top of the FRP composite girders are not permitted. This is to prevent post cured FRP girders approaching its glass transition temperature \( T_g \).

16.6 *Material properties*

16.6.1 General

Designers shall always seek specialist advice from the polymer, reinforcement and manufacturing supplier, or a technical specialist.

FRP composite girders are manufactured in different ways. Examples are not limited to:

- assembly of only FRP sections by means of suitable adhesives
- assembly of FRP sections, FRP panels and steel in a hybrid section
- assembly of FRP section, steel, concrete, lightweight core into a hybrid, and
- by means of a vacuum assisted resin infusion process.

16.6.2 Reinforcement

16.6.2.1 Fibres

Only the following glass fibre types are permitted in FRP composite girders. Minimum properties of fibre before processing shall be as specified in Table 16.6.2.1.

- E-glass
- ECR-glass, and
- S-glass.

E-glass shall not be used in the following applications:

- members in salt-rich arid areas
- sea water – tidal or splash zone, and
- soft or running water.

| Table 16.6.2.1 – Minimum of fibres before processing |
|---------------------------------|--------|--------|--------|
| Fibre Properties                | E-glass| ECR-glass| S-glass|
| Specific Gravity                | 2.54   | 2.71    | 2.47   |
| Tensile Strength MPa (22°C)     | 3400   | 3300    | 4600   |
| Tensile Modulus GPa (22°C)      | 72     | 72      | 88     |
| Elongation %                    | 4.8    | 4.8     | 3.0    |
| Coefficient of Thermal Expansion \( 10^{-6} \)/°C | 5.0    | 5.9     | 2.9    |

16.6.2.2 Rovings

Use of rovings shall comply with ISO 2797 or equivalent.
16.6.2.3 Mats – continuous filament mats

a) Use of continuous filament mats shall comply with ISO 2559 or equivalent.

b) Non continuous, chopped strand mat shall not be used for structural purpose. The glass fibre in the chopped strand mats shall not be included in any calculations of structural performance.

16.6.3 Polymer matrices

Selection of polymer matrices shall comply with Section 3.2 of Eurocomp Design Code.

Knowledge of the operating temperature is vital in selecting an appropriate stable resin system. If the service temperature is closer to the heat distortion temperature, as with all polymers loss of stiffness and significant creep will occur.

The selection and design of polymer resins is a critical aspect of the design of fibre composite girders.

16.6.3.1 Acceptable resin types

The following types of resins are acceptable to be designed according to properties and limits in accordance within the Eurocomp Design Code:

- polyester resins
- vinyl ester resins
- phenolic resins, and
- epoxy resins.

The allowable material properties of resins shall be as shown in Table 16.6.3.1.

<table>
<thead>
<tr>

16.6.4 Core materials

A general description of the core material shall be submitted. It shall be demonstrated that the core materials used are suitable for the intended purpose. Core materials shall be compatible with the resin used and the manufacturing system. They shall not impair the curing of the laminating resins.
16.6.5 Gel coats

Gel coats shall be considered non-structural. Gel coat shall be appropriate for the structure and to suit particular environment.

Gel coats are applied to the surface of a composite structure to:

- filter out ultraviolet radiation and improve weathering
- add flame retardency to provide an increased thermal barrier
- improve erosion
- provide an increased barrier to moisture, and
- provide colour scheme and improve general finish.

16.6.6 Laminates

Laminates to be incorporated into FRP composite girders shall be designed according to Clause 4.10 of Eurocomp Design Code.

The laminates in bridge beams shall be arranged such that all major loads are carried by fibres.

16.6.7 FRP profiles

FRP profiles shall have a minimum 60% of fibre content by weight.

Minimum properties of FRP composite profiles shall be as shown in Table 16.6.7.

16.7 Design and detailing

16.7.1 Design for ultimate limit state

The ultimate strength of the girder shall satisfy the following:

- Characteristic tensile strain of unidirectional lamina shall be 0.015.
• Glass Fibre Reinforced Polymer (GFRP) components shall not exceed their Ultimate Limit State (ULS) capacity at a strain of 0.009 (60% of the characteristic tensile strain of unidirectional lamina = 0.6 x 0.015) as shown in Figure 16.7.1.

• FRP composite structures shall be designed for ultimate limit states according to Clauses 2.3.2 and 4.1 of Eurocomp Design Code.

Figure 16.7.1 – ULS and SLS strain limitations

16.7.2 Design for serviceability limit state

At the Serviceability Limit State (SLS), the strain in the GFRP girders shall not exceed 0.001 as shown in Figure 16.7.1.

Fibre composite structures shall be designed for SLS according to Clauses 2.3.4 and 4.2 of Eurocomp Design Code.

16.7.3 Warning of failure

Structures made with FRP composites shall be designed to give reasonable and adequate warning of failure before reaching an ultimate limit state.

Most FRP composites exhibit limited or no ductile behaviour beyond the linear stress limit. The design shall ensure that a serviceability limit state is reached before its ultimate limit state for the mode of failure being considered. The serviceability limit state to be exhibited may include:

• excessive deflection / deformation
• buckling or wrinkling, and / or
• local damage / failure.

16.7.4 Failure modes

a) Failure mode due to adhesive separation shall not be permitted.

b) Resin and adhesive dominated failure modes shall not be permitted.
Delamination is a common failure mode in FRP composite structures and the Designer shall provide adequate details in the design to confine the structure against catastrophic delamination.

16.7.5 Design for stability

Fibre composite girders shall be designed for stability according to Clause 4.7 of Eurocomp Design Code.

Girders shall be designed to be:

- independent, and not require lateral stiffeners, and
- torsionally stable in the lateral direction.

16.7.6 Deformability of FRP composite girders

FRP composite girders do not demonstrate ductile behaviour as FRP does not yield like steel. FRP girders shall be designed to exhibit substantial deflection before failure. To ensure a sufficient level of safety between serviceability and ultimate limit states, an adequate level of deformability has to be shown. The deformability factor of FRP composite girders shall be assessed as noted below. (ref. Canadian Highway Bridge Design Code (CHBDC) 2006):

$$\text{Deformability Factor} = \frac{\Psi_u M_u}{\Psi_s M_s}$$

where $\Psi M$ corresponds to Curvature and Moment capacity at ultimate and serviceability states.

The serviceability strain state corresponds to a maximum compressive strain in the concrete or FRP of 0.001 and tensile strain in FRP of 0.001. The deformability factor shall be greater than 4 for rectangular sections or 6 for T sections (as per CHBDC). For any other shapes, deformability factor shall be determined by the designer.

16.7.7 Durability

FRP composite components shall be designed using a degraded $E$ value estimated for the end of the design life.

FRP composites generally have excellent acid resistance compared with steel. But, FRP composites are prone to deterioration in environments with high concentrations of acid or alkali. Creep rupture and stress corrosion are two consequences of exposure to acidic environments. UV resistance of some resins is low and it is recommended that appropriate measures be taken by the manufacturer to shield the FRP composite girders from deterioration.

The only true test for durability is the in-service highway bridge. FRP composites deteriorate with environmental exposure and repeated application of load. This degradation of modulus of Elasticity, $E$, has been measured experimentally in accelerated durability tests for various FRPs.

16.7.8 Fire resistance

a) Fire retardant coating, fire retardant resin or fire retardant resin additives shall be provided for FRP composite girders. FRP girders shall be fabricated to meet Fire Resistance Level 90/-/- according to Clause 2.14 of AS 1530.4.
b) Fire testing on FRP composite girders shall be carried out if instructed. Testing shall be in accordance with Section 2 and 6 of AS 1530.4. The serviceability limit state load shall be used for fire test in accordance with Clause 2.12.1 of AS 1530.4.

FRP composites are not inherently fire-resistant. Combustibility, spread of flame, changes in mechanical properties and toxic fumes need to be considered.

Performance in a fire is generally improved by increased glass fibre content. Using fire retardant resins or resin additives improves fire retardation.

Fire testing is not normally required, but may be specified on certain projects/systems.

16.7.9 Thermal expansion

a) Thermal coefficients derived from testing by the Manufacturer shall be used in the design of FRP girders.

b) The appropriate thermal gradient relevant to the environment that the FRP girders are exposed to shall be incorporated in the design.

Coefficient of thermal expansion of FRP composites vary due to several material constituents in the manufacture of FRP girders. The effects of difference in coefficient of thermal expansion between different materials need to be considered. These includes adhesives, steel, concrete, cores and FRP.

16.7.10 Creep and shrinkage

a) Creep of FRP girders shall be incorporated into the design according to Clause 4.12 of Eurocomp Design Code.

b) Adequate measures shall be taken to account for shrinkage of FRP girders in the design.

c) Changes in shape, hogging, sagging and any member distortion are not permitted above the tolerance provided in Table 7.4, MRTS59 Manufacture of Fibre Reinforced Polymer (FRP) Composite Girders. Dimensional stability shall be maintained at all stages. These stages include production, storage, and installation on site and in service for the design life.

16.7.11 End zones design and connections

16.7.11.1 End zone

a) The Designer shall determine the performance of FRP girders at the supports.

b) The Designer shall ensure that the end zone design is checked for bearing, web crushing, shear, and buckling. The end zone design shall have sufficient length to accommodate future trimming to reduce the girder length to suit the actual span.

c) The design shall be verified and certified by testing.
End Zone is generally a critical part for a FRP girder which needs more detailed design compared with the general section design as it involves much more complex failure mechanisms including shear, crushing and buckling.

16.7.11.2 Connections

a) Connections for FRP composite girders shall be designed according to Clause 5 of Eurocomp Design Code.

b) Bolted joints for shear and tension shall be designed according to Clause 5.2 of Eurocomp Design Code.

c) Bonded connections shall be designed according to Clause 5.3 of Eurocomp Design Code.

d) The adequacy of the connection shall be determined by testing.

e) The FRP composite girder design shall be accompanied by relevant connection details. FRP composite girder supplier / designer shall submit the relevant calculations to Transport and Main Roads for review prior to manufacture of FRP girders.

f) Bolted connections shall be used for all main and secondary member connections.

g) Steel bolts shall comply to MRTS78 Fabrication of Structural Steelwork.

16.7.11.3 Cutting and drilling

a) FRP composite girder design shall identify the drilling and sawing locations.

b) Cutting of girders will expose fibres. Cut edges shall be sealed by the site crew as directed by the fabricator.

c) FRP composite girder design shall have provision to drill on site, as well as at the factory. All cutting and drilling shall be conducted by adequately trained personnel.

FRP members need site cutting, and the internal reinforcement may be designed to terminate in the end zone. Due to girder fixing details, this may cause potential cracking at the reinforcement termination points under the negative bending moment conditions especially when a long vehicle passes over a pier.

The stress concentration at the edge of solid packers may be critical for some hollow section designs. For these specific issues, the Designer needs to ensure all the risks have been addressed through proper design, for example using proper rubber strip bearings.

16.7.11.4 Holes in FRP girders

Holes in FRP composite girders shall be plugged with an approved sealant to:

- avoid ingress of water
- prevent bearing strength reduction due to water ingress, and
- prevent tearing of fibre due to bolt movement.

FRP composite girders shall meet the requirements of ULS and SLS, with holes considered.
16.7.11.5 Edge distance

Minimum edge distance for bolts shall be three times the bolt diameter from the nearer edge of the hole to the edge of the member.

16.8 Design requirements

a) FRP composite girders to be used as superstructure in a new bridge shall be designed in accordance with Section 16.4 to 16.7 and additional requirements stated in Section 16.9.

b) FRP composite girders that replace timber girders in a timber bridge shall be designed in accordance with Section 16.4 to 16.7 and additional requirement stated in Section 16.10.

16.9 Additional requirements FRP composite girders for new bridges

Section 16.9 is applicable only for FRP girders for new bridges. Refer Section 16.10 for additional requirements for FRP girders for timber bridges.

16.9.1 Traffic loads on new bridges

The loading requirements for design of FRP composite girders for New Bridges shall comply with AS 5100.2.

16.9.2 Load combinations and load factors for design of FRP composite girders

a) The most adverse design load combination shall be determined according to AS 5100.2.

b) Load factors and accompanying lane factors for design of FRP composite girders on bridges shall be in accordance with AS 5100.2.

c) The load factor ($\gamma_d$) for dead load of structure shall be 1.2 for ULS and 1.0 for SLS designs.

d) The dynamic load allowance ($\alpha$) for traffic loads shall be applied to both ultimate and serviceability limit states.

e) The design action is equal to $(1+\alpha) \times$ the load factor $\times$ the action under consideration. Dynamic load allowance ($\alpha$) shall be in accordance with AS 5100.2.

16.9.3 Method of structural analysis and design

Structural analysis and design shall comply with AS 5100.

16.9.4 Design for strength

a) The FRP composite girders shall be designed for strength as follows:

i. the Design Action Effects $S^*$ (required strength due to factored loads) shall be determined by structural analysis for the appropriate load combinations as stipulated in AS 5100.2, and

ii. the Ultimate Strength ($R_u$) shall be determined on strain compatibility, internal force equilibrium and controlling mode of failure.

For the Ultimate Limit State, the Design Strength ($=\phi R_u$) shall satisfy the following:

$$\phi R_u \geq \frac{S^*}{k}$$

Where, the strength reduction factor, $\phi = 0.25$ and $k = 0.75$. 
Additional reduction factor $k$ is introduced to compensate for lack of existing knowledge to correlate new design capacity with actual capacity.

16.9.5 Deflection

The deflection limits of the bridge shall be in accordance with AS 5100.

16.9.6 Design life

The design life for FRP composite girders on new bridges shall be 100 years.

16.9.7 Fatigue for FRP girders on new bridges

FRP composite girders for new bridges shall be designed according to Clause 6.9 of AS 5100.2.

16.9.8 Vibration

FRP composite girders shall be designed for vibration according to Clause 12 of AS 5100.2.

16.10 Additional design requirements for FRP composite girders on existing timber bridges

Section 16.10 is applicable only for design of FRP composite girders on timber bridges. This section shall not apply to FRP composite girders to be used in new bridges. Refer Section 16.9 for FRP composite girders for new bridges.

FRP composite products intended for timber bridge replacement shall be assessed in a holistic manner, not in isolation. When designing FRP composite girders, the Designer shall include relevant:

- connection details
- installation procedures, and
- working drawings.

FRP composite girders shall satisfy both structural and functional requirements.

16.10.1 Performance criteria

FRP composite girders intended for timber replacement shall comply to the performance criteria shown in Table 16.10.1.

**Table 16.10.1 – Performance criteria for existing Transport and Main Roads timber bridges**

### 16.10.2 Fatigue design of FRP composite girders on timber bridges

FRP girders for timber bridge renewal shall be designed to $1.0 \times 10^6$ fatigue cycles and spike load of 100% service load at every $0.2 \times 10^6$ cycles.

### 16.10.3 Design Life of FRP composite girders on timber bridges

The design life for FRP composite girders on timber bridges shall be 30 years.
17 Small drainage structures

This section is applicable for small drainage structures such as culverts, culvert headwalls, drainage pits, road side kerb inlets and other precast road side drainage elements.

Bridges shall be designed in accordance with Chapter 1 to 7 of this document.

17.1 Design requirements for culverts

Refer the department’s Road Drainage Manual: Chapter 9: Culvert Design for design requirements of all culvert types. Following list of Standards apply:

- Design for installation of pipe culverts shall be in accordance with MRTS03 Drainage, Retaining Structures and Protective Treatments and AS/NZS 3725: Design for installation of buried concrete pipes.
- Metal culverts shall be designed to AS/NZS 2041 (set): Buried corrugated metal structures. Refer Road Drainage Manual for limitations to use metal culverts.
- Design of precast reinforced concrete box culverts shall be in accordance with MRTS24 Manufacture of Precast Concrete Culverts and AS 1597 (series): Precast reinforced concrete box culverts.
- Steel reinforced concrete pipes shall be designed in accordance with MRTS25 Manufacture of Precast Concrete Pipes and AS/NZS 4058: Precast concrete pipes (pressure and non-pressure).
- Fibre reinforced concrete pipe culverts shall be designed in accordance with MRTS26 Manufacture of Fibre Reinforced Concrete Drainage Pipes and AS 4139: Fibre reinforced concrete pipes and fittings.
- Cast insitu box culverts shall be designed to AS 5100 (series): Bridge design.
- Design for lifting of precast concrete components shall be in accordance with MRTS72 Manufacture of Precast Concrete Elements.
- All drainage structures must be readily accessible for cleaning and maintenance purposes.

17.2 Design life for small drainage structures

Minimum design life for drainage structures shall be as follows:

- a) Box Culverts including headwalls - 100 years
- b) Pipe culverts including headwalls - 100 years
- c) Drainage pits, depth less than or equal to 5.0 m - 50 years
- d) Drainage pits, depth greater than 5.0 m - 100 years

Table 17.2 – Other drainage structures with design life less than 100 years

### Chapter 17: Small drainage structures

#### Standard Drawing Number | Detail | Design Life (years)
--- | --- | ---
1310 | Concrete Gully-Field Inlet Type 2 | 50
1311 | Components except drainage pits | 50
| Drainage pits | Refer Clause 17.2 | 50
1312 | Components except drainage pits | 50
| Drainage pits | Refer Clause 17.2 | 50
1313 | Precast Lintel | 50
1321 | Components except drainage pits | 50
| Drainage pits | Refer Clause 17.2 | 50
1322 | Components except drainage pits | 50
| Drainage pits | Refer Clause 17.2 | 50
1442 | Components except drainage pits | 50
| Drainage pits | Refer Clause 17.2 | 50
1443 | Roadway Type Precast Inlet Units on Grade | 50
1444 | Roadway Type Precast Inlet Units in Sag | 50
1446 | Kerb Ramp - Ramped Kerb Crossing | 50
1459 | Components except drainage pits | 50
| Drainage pits | Refer Clause 17.2 | 50

#### 17.3 Barriers for culverts

Barriers shall be provided to culverts in accordance with the relevant departmental Standard Drawings and *Road Planning and Design Manual*.

#### 17.4 Approach settlement adjacent to large culverts

For large culverts with the height greater than or equal to 6.0 m, the calculated residual settlement on the approaches shall be controlled using selected fill material or ground improvement methods, both specified by the project geotechnical engineer and any residual settlement is accepted by the project pavement design engineer. The short term and long term settlement control measures shall be submitted to Director (Geotechnical) for review and acceptance.

#### 17.5 Structural requirements for existing culverts

Refer to the department’s *Road Drainage Manual*: Chapter 9: Culvert Design
18 Design of motor grids

18.1 Design life

Minimum design life for motor grids shall be 50 years.

18.2 Motor grid design criteria

Motor grids shall be designed in accordance with Technical Note 18 Design Criteria for Motor Grids. The department’s standard motor grids are shown in Standard drawings 1561, 1562, 1563, 1564 and 1565.
19 Technical notes

In addition to the design guideline provided in this document, Technical notes in the link below are applicable as appropriate. Where this document and the Technical notes are disagree, this document shall be considered as most updated departmental guideline.
